Title: Developmental origin and dynamics of Hoxb8 microglia

Authors: *D. VAN DEREN, JR, B. XU, M. ECONOMO, M. WACHOWIAK, P. TVRDIK, G. SPANGRUDE, M. CAPECCHI;
Univ. of Utah, Salt Lake City, UT

Abstract: Microglia are the innate immune cells that constantly survey the environment of the central nervous system (CNS). Recently, it was demonstrated that microglia originate from yolk sac-derived macrophages during primitive hematopoiesis and subsequently infiltrate the embryonic brain (Ginhoux et al. 2010). However, it is unclear whether this group accounts for the total adult microglia population following development. We have addressed this question using a Hoxb8-IRES-Cre reporter mouse line because the Hoxb8 lineage includes a subset of microglia that only appear postnatally in the brain parenchyma (Chen et al. 2010). Using the Hoxb8-IRES-Cre mouse line to report cell lineage, we show that a substantial population (~30%) of postnatal cortical microglia arises independently of the yolk sac, during definitive hematopoiesis. We performed FACS analysis of the yolk sac and anterior and posterior poles of the embryos harvested from Hoxb8-IRES-Cre+/-; Rosa26-tdTomato (Ai14)+/-; Cx3cr1-GFP+/- triple transgenic mice at embryonic (E) stages E8.5 - E10.5. Our data show that less than 10% of CD45+ cells in the yolk sac during the critical stage of primitive macrophage formation (E8.5) are positive for the Hoxb8 cell lineage (Hoxb8+). From our analysis, it also appears that Hoxb8+ cells arise earlier than Cx3cr1+ cells, and are of distinct origins initially. The CD45+ Hoxb8+ cells are mostly c-kit positive at this stage, indicating that this population represents hematopoietic progenitor cells. During definitive hematopoiesis, the percentage of Hoxb8+ cells rises continuously and accounts for 100% of the peripheral blood and bone marrow cells, and about 40-50% of cortical microglia in the adult brain parenchyma. We have established that the bulk of infiltration of Hoxb8+ microglia in the brain occurs during the first postnatal week. Using live 2-photon microscopy, we delineated their transition from the meningeal space to the

neonatal cortex. While both Hoxb8+ and Hoxb8- microglia appear to have similar motility and speed of their processes, their response to neonatal brain injury is more exaggerated in the Hoxb8+ population. This study provides evidence for a separate class of microglia, Hoxb8+ microglia, which derives from definitive, not primitive, hematopoiesis and infiltrates the brain postnatally.

Title: Hoxb8-positive microglia have distinct developmental and physiological properties

Authors: *S. DE[1], N. NAGARAJAN[1], B. XU[1,3], E. PEDEN[1], P. TVRDIK[1,2], M. CAPECCHI[1,2,3];
[1]Human Genet., [2]The Brain Inst., Univ. of Utah, Salt Lake City, UT; [3]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: *Hoxb8* mutant mice exhibit an excessive grooming behavior which is manifested by localized hair removal and self-inflicted skin lesions, a behavior similar to the OCD-spectrum disease trichotillomania (Chen et al., 2010; Greer and Capecchi, 2002). Pathological grooming, which depends on specific brain circuits, can be restored in *Hoxb8* deficient mice to a normal grooming pattern following wild type bone marrow transplantations, suggesting hematopoietic origin of this behavior. The predominant cells in the brain derived both from the *Hoxb8* lineage are certain microglia, designated as the "*Hoxb8*$^{+}$ microglia". We are interested in elucidating the specific roles of *Hoxb8* microglia in neural circuits. For unequivocal cell identification, we used *Hoxb8*-IRES-Cre$^{+/-}$; *Rosa26*-tdTomato (Ai14) $^{+/-}$; *Cx3cr1*-GFP$^{+/-}$ triple transgenic mouse model, in which all microglia are labeled with GFP, and the *Hoxb8*$^{+}$ microglia are also labeled with tdTomato. We show that the *Hoxb8* microglia populate the brain parenchyma after birth with a peak density around postnatal day 8 (P8). As determined by EdU incorporation, proliferative rates in both *Hoxb8*$^{-}$ and *Hoxb8*$^{+}$ populations are relatively high during the first postnatal week, and similar in both subtypes. This indicates that the increase in the relative *Hoxb8*$^{+}$ population density is due to increased cortical infiltration rather than selective proliferative advantage.

Interestingly, *Hoxb8*$^{+}$ display several morphological differences compared to *Hoxb8*$^{-}$ microglia at several developmental stages, such as greater overall length of the projections and branching density on individual projections. When challenged in an injury model (induced by facial nerve axotomy), the non-*Hoxb8* microglia show higher degree of activation compared to the *Hoxb8* cells. Our data suggests that *Hoxb8*$^{+}$ microglia have unique functions, which cannot be compensated by the non-*Hoxb8* microglia. Elucidating the differences between the *Hoxb8* and non-*Hoxb8* population will help to identify specific roles that contribute to the mutant behavior.

Title: New function of synapses: Synaptic input as a directional cue for migrating interneuron precursors

Authors: *A. K. WEFERS[1,2], C. HABERLANDT[2], J. J. L. VAN DER WANT[3], C. STEINHÄUSER[2], K. SCHILLING[1], R. JABS[2];

Abstract: During CNS development, interneuron precursors have to migrate extensively before they can integrate in their specific microcircuits. The mechanisms that assure interneuron dispersal and interneuron/projection neuron matching during histogenesis remain largely elusive. We combined time-lapse video-microscopy and electrophysiological analysis of the nascent cerebellum to address this issue. We found that cerebellar interneuronal precursors regularly show spontaneous postsynaptic currents, indicative of synaptic innervation, well before settling

in the molecular layer. Ablation of synaptic communication by blocking vesicular release in acute slices of developing cerebella slows migration and impedes the directionality of interneuronal precursors in transit. These results establish an unprecedented early synaptic innervation of migrating neuronal precursors and demonstrate a role for synapses in the regulation of migration and pathfinding.

Title: Origin and migration of GnRH neurons in early human embryonic development

Authors: *F. CASONI[1], F. LUZZATI[2], F. COLLIER[3], V. PREVOT[4], P. GIACOBINI[4]; [1]Inserm, Jean-Pierre Aubert Res. Center, U837, Lille, France; [2]Neurosci. Inst. Cavalieri Ottolenghi, Torino, Italy; [3]Gynaecology Service, Ctr. Hospitalier of Lille, Hosp. Jeanne de Flandre, Lille, France; [4]INSERM, Jean-Pierre Aubert Res. Center, U837, Lille, France

Abstract: Gonadotropin-Releasing Hormone (GnRH) neurons are the central regulators of sexual development and reproduction in all vertebrates. During embryonic development, GnRH neurons differentiate in and migrate from the vomeronasal organ (VNO) to the ventral forebrain where they will later become integral members of the hypothalamic-pituitary-gonadal axis. Although different studies have shown that GnRH mature similarly in different vertebrates, the embryonic development of GnRH cells in human embryonic forebrain has not been fully characterized. Here we have examined the initial stages of GnRH cell differentiation, the chemical makeup of the migratory route and the intracerebral distribution of GnRH neurons in the embryonic human telencephalon during the first trimester of gestation. For the first time, we described subpopulations of neurons and ensheathing cells emerging from the olfactory placode by 5 weeks and half of gestation, which precede the emergence of the GnRH neurons and olfactory axons. Using immunohistochemistry and 3D-reconstruction analysis, we provide evidence that the development of the human GnRH system begins earlier than previously

thought and we characterize a new intracerebral migratory pathway of GnRH neurons never described in other species. Finally, we performed a quantitative analysis of GnRH cell distribution throughout the entire migratory route and provide evidence that early human foetuses contain a complement of GnRH cells much greater than previously thought.

Title: Negr1 is required for transition of migrating pyramidal neurons from layer V to layer II/III of the mouse cerebral cortex

Authors: *J. SZCZURKOWSKA[1], F. PISCHEDDA[2], M. SCHÄFER[3], G. PICCOLI*[2], L. CANCEDDA*[1];
[1]Neurosci. and Brain Technologies, Inst. Italiano Di Tecnologia, Genoa, Italy; [2]CNR Inst. of Neurosci. and Dept. of Pharmacol., Univ. of Milan, Milan, Italy; [3]Dept. of Anesthesiol., Univ. Med. Ctr. of Mainz, Mainz, Germany

Abstract: The mammalian cerebral cortex is a remarkably complex structure with unique laminar organization. The establishment of a functional neural circuitry in the cerebral cortex requires this lamination, which is achieved through directional migration of neurons during perinatal development. Indeed, newborn pyramidal neurons migrate along radial glia fibers, in an inside-out manner to create the six-layered structure of the neocortex. Improper neural migration can lead to cell death and/or ectopic positioning with functional consequences on proper wiring in the neuronal network. Common knowledge indicates cell adhesion molecules (CAMs) as essential for proper neural migration.
Neuronal growth regulator 1 (Negr1) protein is a member of IgLON family belonging to immunoglobulin superfamily of CAMs. Negr1 is highly expressed in the cerebral cortex, hippocampus and cerebellum, and its expression increases gradually during postnatal development. Interestingly, NEGR1 gene mutations have been recently associated to autism, a neurodevelopmental disorder characterized by defective neuronal circuit formation and sensory abnormalities. So far, few in vitro studies have suggested a role for Negr1 in neurite outgrowth, but nothing is known about Negr1 function in in vivo neurodevelopment. To address this issue,

we took advantage of the in utero electroporation technique to acutely alter the expression levels of Negr1 in the developing cerebral cortex in vivo. We downregulated Negr1 expression by RNA interference (siRNA) in late-born pyramidal neurons, and found that Negr1 siRNA caused defects in radial migration of these neurons to the superficial layers of the neocortex. In particular, we found ectopic positioning of a number of Negr1 siRNA-expressing neurons. Interestingly, these ectopic neurons were located almost exclusively at the border between layer 5 and layer 4, and this effect was restricted only to the somatosensory cortex.
Taken together, these data suggest that Negr1 is necessary for proper neuronal migration of pyramidal neurons in the somatosensory cortex, indicating a possible role for this complex in neurodevelopmental disorders such as autism.

Title: Dorsal migration and formation of the secondary, permanent chain of sympathetic ganglia as revealed by confocal time-lapse analysis in chick

Authors: *J. C. KASEMEIER[1], F. LEFCORT[3], P. M. KULESA[2];
[1]Kulesa Lab., [2]Stowers Inst., Kansas City, MO; [3]Cell Biol. and Neurosci., Montana State Univ., Bozeman, MT

Abstract: The sympathetic nervous system (SNS) plays a vital role in maintaining homeostasis. In conjunction with the parasympathetic nervous system, all involuntary, autonomic functions of the vertebrate organism are regulated, including breathing, blood flow and heart rate. All sympathetic neurons differentiate from the trunk neural crest, a pluripotent, heterogeneous cell population that gives rise to the vast majority of the peripheral nervous system, including dorsal root ganglia, sympathetic and parasympathetic ganglia and enteric nervous system. After arriving at the dorsal aorta, neural crest cells respond to cues secreted by the dorsal aorta, primarily BMP-

4, that induce their differentiation to sympathetic neurons. Strikingly, primary sympathetic ganglia (SG) form as discrete transient structures in a chain along the vertebrate axis. Within hours of their formation, sympathetic precursors migrate dorsally towards the ventral surface of the DRG, and form the permanent, secondary chain of SG. The cellular and molecular mechanisms that mediate the dorsal migration and formation of the secondary SG are largely unknown, most likely due to the ventral location deep within the embryo. Using transverse slice culture and confocal time-lapse microscopy, we detail the events involved in secondary SG formation. Interestingly, the primary SG move as a cohesive cluster during their dorsal migration, and use extensive cell-cell contacts among SG cells before re-condensing into ganglia. Filopodial extensions from migrating sympathetic neurons span over 100um in length and contact the forming spinal nerve. Tissue ablation of the spinal nerve results in disrupted dorsal migration. Repositioning of the spinal nerve leads to filopodial extensions from SG cells entering known inhibitory regions to interact with the newly positioned spinal nerve. These data indicate cell-cell and cell-environmental interactions are important for proper SG positioning and development.

Neurology, Dept. of Clin. Neurosci., Karolinska Institutet, Karolinska Univ. Hosp., Stockholm, Sweden

Abstract: Oligodendrocytes are the myelinating cells of the CNS and are essential for proper brain function as they produce the myelin sheath, which is critical for fast axonal conduction and survival of the axons. Myelination has been observed to be modulated by experience and believed to contribute to neural plasticity. Although lost myelin can be regenerated, this remyelination process is often incomplete, resulting in neurological impairment. Studies in experimental animals have shown a continuous generation of oligodendrocytes in the adult brain. However, to what extent this event occurs in the adult human brain remains elusive as methods employed in experimental animals, such as paradigms with labeled nucleotide analogs are not possible to apply in humans.
We have assessed the dynamics of oligodendrocyte generation and myelination in the corpus callosum of the human brain. By measuring the integration of 14C, derived from nuclear bomb testing during the Cold War, in genomic DNA, we found that there is addition, and a small exchange, of oligodendrocytes until myelination is completed in early adulthood. The prospect of ongoing oligodendrogenesis is of particular interest as this is the main cell population affected in multiple sclerosis. Consequently, understanding the occurrence of generation of oligodendrocytes in the physiological and pathological brain may further our knowledge regarding tissue homeostasis and disease pathologies. Furthermore, the occurrence of such event may be a potential target for establishing new therapeutic intervention aiming at affecting this process in brain pathologies.

Biol., Univ. of Pennsylvania, Philadelphia, PA; [4]Psychiatry, [5]Ctr. for Mitochondrial and Epigenomic Med., Children's Hosp. of Philadelphia, Philadelphia, PA; [6]Pathology, Brigham and Women's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Patients with mitochondriopathies can present with epilepsy and autism: both disorders in which cortical interneuron dysfunction is implicated. The early onset of autistic or epileptic features in children with mitochondrial disease along with the association of these features with interneuron dysfunction suggest mitochondria may play essential roles in interneuron development. Tangential migration of interneurons from the basal forebrain into the overlying cerebral cortex is likely to be an energetically demanding process, however little is known regarding a possible role for mitochondria in neuronal migration. We hypothesized that mitochondrial function is crucial to interneuron migration, and that this function influences tangential migration to a greater extent that the radial glial guided migration of cortical projection neurons. To test this hypothesis, we used a combination of explant, and organotypic slice culture in the murine developing nervous system to investigate function of mitochondria in normal interneuron migration.
Immunohistochemistry and live imaging data suggest that mitochondria cluster in specific subcellular regions of migrating interneurons. We find this localization is dynamic depending on the cell's migrational morphology. Pharmacologic and genetic targeting of Adenosine nucleotide transporter 1 and 2 (Ant1, Ant2) in migrating interneurons result in abnormal trailing process behavior, shifts in centrosome position, and reduced migration, indicating a role for mitochondria in rear retraction and polarity, and that mitochondrial function is essential for interneuron migration. Expression of a dominant negative form of Miro1, a molecular motor adaptor allowing for mitochondrial movement in migrating interneurons results in reduced migration rates, but cause increased direction changes, reducing their ability to reach the cortex. These data suggest that interneuron migration is sensitive to perturbations in mitochondrial metabolism, and provide a potential pathogenesis for the neurocognitive phenotypes found in various mitochondrial disorders.

Title: Excitatory cortical neurons are classified into two distinct groups according to their initial axonal direction

Authors: *Y. HATANAKA[1,2], K. YAMAUCHI[3], T. NAMIKAWA[4], Y. KAWAGUCHI[1,2];
[1]Natl. Inst. for Physiological Sci., Okazaki, Aichi, Japan; [2]CREST, JST, Tokyo, Japan; [3]Grad Sch. of Frontier Biosciences, Osaka Univ., Suita, Japan; [4]Grad Sch. of Biol. Sciences, Nara Inst. of Sci. and Technol., Ikoma, Japan

Abstract: Excitatory cortical neurons are output neurons whose axons project subcortically or intracortically (i.e. ipsilateral cortico-cortical and callosal projection), although there are some exceptions such as certain local-circuit neurons. Basically, subcortially projecting neurons are located in deep layers, intracortically projecting neurons are located in upper layers and to some extent in deep layers, and local-circuit neurons are located between these two layers. Recently, we have shown that embryonic day (E) 12.5 labeled ventricular zone (VZ) cell-progeny, which give rise to deep layer neurons, initiate directed axon outgrowth in the intermediate zone (IZ) before radial migration into the cortical plate (CP) (Hatanaka and Yamauchi, Cereb Cortex 23,105, 2013). This observation prompted us to examine whether all excitatory cortical neurons initiate directed axon outgrowth in the IZ, and if so, how initial axonal extension is associated with the mature projection pattern. To address this question, we labeled mouse VZ cells in the lateral cortex at several developmental stages (from E11.5 to E15.5) by *in utero* electroporation, and examined axonal formation by their progeny, as well as marker expression and the layer distribution of labeled cells at later stages. We found that all labeled CP cells and many IZ cells exhibited long tangential processes in the IZ. Notably, these processes only extended either laterally or medially, and their direction was age-dependent: the vast majority of the processes derived from earliest emigrants from E12.5 or earlier VZ progeny extended laterally, while those from E13.5 or later extended medially toward the corpus callosum. Marker expression of the labeled cells was consistent with the idea that the former is a subcortical projection population and the latter a callosal projection population. At postnatal 3 weeks, E12.5 labeled cells were distributed mainly in deep layers, while E13.5 or later labeled cells were distributed in upper layers including layer IV and to some extent in deep layers. These results indicate that excitatory cortical neurons share a common trait of directional axon outgrowth in the IZ, and that they can be classified into two distinct groups according to their axonal direction; a subcortical (lateral) projection group, which develops axons earlier, and a callosal (medial) projection group, including intracortical projection neurons in deep layers, local circuit neurons in layer IV, and neurons in upper layers. Although some of them may prune their initial projections during

maturation, it seems that the formation of callosal projections is the default mode of the latter group.

Title: Sp9 is required for the normal migration of cortical interneurons

Authors: *Q. ZHANG, Y. ZHANG, Z. LIU, J. LI, Z. YANG;
Inst. of Brain Sci. ,Fudan Univ., Shanghai, China

Abstract: The neocortex contains two main neuron populations, the excitatory glutamatergic projection (pyramidal) neurons and the GABAergic inhibitory interneurons, which constitute about 20% of all neocortical neurons. Neocortical projection neurons are born during embryogenesis in the ventricular zone of the dorsal pallium (neocortex), whereas neocortical interneurons are derived from the subpallium (including the MGE and LGE/CGE) and reach the neocortex by tangential migration. Dlx1/2 homeobox genes are essential for the tangential migration of subpallial-derived GABAergic interneurons to neocortex. However, it remains largely unknown the mechanisms underlying this process. Here, we show that Sp9, a zinc finger gene, is expressed in most (perhaps all) postmitotic GABAergic neurons of the MGE and LGE/CGE. Sp9 is down-regulated when interneurons migrate into the neocortex, therefore mature interneurons in the neocortex do not express Sp9. Interneurons and medium spiny neurons in the neonatal striatum also express Sp9; however, Sp9 is not expressed in the adult striatum. We also show that Sp9 is required for the normal tangential migration of neocortical GABAergic interneurons.

Title: Cytoskeleton arrangement, associated proteins and their relationship with the migration/invasion pattern of culture pituitary adenoma cells

Authors: *D. AVILA[1], M. MENDOZA[1], A. ORTIZ-PLATA[2], E. AGUIRRE-BENÍTEZ[3], M. GONZÁLEZ DEL PLIEGO[3];
[1]Dept. of Physiology, Biophysics and Neurosciences, Ctr. For Res. and Advanced Studies I.P.N. (CINVESTAV), México D. F., Mexico; [2]Lab. of Exptl. Neuropathology, Nacional Inst. of Neurol. and Neurosurg. "Manuel Velazco Suaréz", México D. F., Mexico; [3]Dept. of Embryology, Autonomous Natl. Univ. of Mexico, México D. F., Mexico

Abstract: Introduction
Pituitary adenomas are generally considered benign, slow-growing and rarely metastasize, but some cells may migrate infiltrating adjacent tissues. Cell migration requires coordinated communication between the actin cytoskeleton, intermediate filaments and tubulin cytoskeleton.
Objective
Characterize the arrangement of the cytoskeleton, adhesion proteins and the relationship of the cytoskeleton arrangement with the migration patterns that the pituitary adenoma cells could adopt.
Methods
Ten macroadenomas were studied, seven invasive and 3 non-invasive. The tumor tissues were donated by the National Institute of Neurology and Neurosurgery, in Mexico City. After surgical removal, a cell suspension was obtained using an enzymatic-mechanical method and the suspended cells were cultured in a three-dimensional system of alginate gel pearls.. The cells were liberated from the alginate gel pearls and were cultured on cover glasses for further immunocytochemical analysis.
Results
We found that cells macroadenomas take two main arrangements of the cytoskeleton: discontinuous cortical rings and a fine mesh, and in uncured filaments in membrane protrusions with small stress fibers, arrangement compatible with the amoeboid-like migration pattern. They arrange their microtubules as a diffuse network, suggesting a deficiency in their secretory activity and in migration directionality. With regard to the intermediate filaments, all cells expressed vimentin and only a few expressed GFAP; both intermediate filaments typically are not expressed in normal secretory cells. These findings suggest that cells acquire a higher elastic

capacity. Interestingly, all the different tumor cells showed poor substrate adhesion. All macroadenomas cells expressed the N-cadherin in cell-cell contact sites and wide-spread in the cytoplasm.
Conclusions
Taken together, these results show that macroadenomas cells organize their cytoskeleton in two ways, as leukocytes, and as mesenchymal cells with low substrate adhesion, besides their invasive capacity. In conclusion invasive-silent-macroadenoma cells in culture adopt a rounded shape with low substrate adhesion and showed tubulin cytoskeleton disorganization suggesting an amoeboid-like migration pattern.

Title: Biochemical and morphological characterization of A2BP1 in the neuronal tissue

Authors: *K.-I. NAGATA, N. HAMADA, H. ITO, I. IWAMOTO, M. MIZUNO, R. MORISHITA, Y. INAGUMA, H. TABATA;
Inst. For Developmental Research, Aichi Human Service Ctr., Kasugai, Japan

Abstract: Background: Ataxin-2-binding protein 1 (A2BP1), which is also termed FOX1 or RBFOX1, is considered to regulate alternative splicing of important neuronal transcripts and has been implicated in neurological/developmental disorders such as autism and mental retardation. In this study, we prepared a specific antibody against A2BP1, anti-A2BP1, and carried out biochemical and morphological analyses of A2BP1 in rat and mouse neuronal tissues.
Results: We prepared a rabbit polyclonal antibody, anti-A2BP1, against full length of mouse A2BP1-A016 isoform, and affinity-purified it. Specificity of the antibody was confirmed with COS7 cell lysates expressing Myc-A2BP1. Anti-A2BP1 recognized both A016 and A030 isoforms in western blotting and detected endogenous A2BP1 in rodent brain tissues during developmental stages. Biochemical fractionation clarified that A2BP1 with ~60 kDa and ~50 kDa were relatively enriched in the synaptosomal and postsynaptic density fractions, respectively. In immunohistochemical analyses, A2BP1 was detected mainly in the nucleus and

weakly in the cell body and dendrites of excitatory neurons in rodent cerebral cortices. In contrast, A2BP1 was not observed in mitotically active progenitor cells in the developing cortices. We then performed immunofluorescence analyses using primary cultured rat hippocampal neurons. In immature 3div neurons, A2BP1 was evenly expressed in the soma, axons and dendrites. Then, as differentiation advances, A2BP1 distribution gradually changed and it came to be enriched in the nucleus. Interestingly, A2BP1 was also observed adjacent to a presynaptic protein, synaptophysin, and a postsynaptic protein, PSD-95, in 20 div neurons. Conclusion: In this study, we carried out biochemical and morphological analyses of A2BP1 by the use of a homemade antibody. The results obtained suggest the role of A2BP1 in the nucleus and near excitatory synapses of differentiated neurons.

Title: Modulation of mouse hippocampal neurogenesis by cyclic nucleotide-gated channels

Authors: M. V. PODDA[1], R. PIACENTINI[1], S. A. BARBATI[1], A. MASTRODONATO[1], D. PUZZO[2], *M. D'ASCENZO[1], L. LEONE[1], C. GRASSI[1];

Abstract: Throughout life adult neurogenesis generates new neurons in the dentate gyrus of hippocampus that play critical roles in learning and memory. There is great interest in identifying physiological and exogenous stimuli able to stimulate this endogenous process because of their potential use for treatment of neurodegenerative diseases entailing cognitive impairment. Aim of the present study was to ascertain the possible role of cyclic nucleotide-gated (CNG) channels in hippocampal neurogenesis.These voltage-independent channels activated by cyclic nucleotides, first described in retinal and olfactory receptors, have been receiving increasing attention for their involvement in several brain functions. We found that the rod-type, CNGA1, and olfactory-type, CNGA2, subunits are expressed in hippocampal neural stem cells (NSCs) in culture as well as in the hippocampal neurogenic niche of adult mice. Pharmacological blockade of CNG channels did not affect NSC proliferation but reduced their differentiation toward the neuronal

phenotype. Addition of 8-Br-cGMP (1 mM) to the culture medium enhanced neuronal differentiation of NSCs and this effect was prevented by CNG channel blockade. In addition, patch-clamp recordings from neuron-like differentiating NSCs revealed cGMP-activated currents that are reminiscent of those flowing through CNG channels. Taken together these data provide novel insights into the role of CNG channels in promoting hippocampal neurogenesis, which may prove to be relevant for stem cell-based treatment of cognitive impairment and brain damage.

Title: Role of γRIMs in the regulation of neuronal arborization

Authors: *K. MICHEL[1], A.-M. OPRISOREANU[1], E. ALVAREZ-BARON[1], C. HOOGENRAAD[2], S. FRANKEN[3], A. BECKER[1], S. SCHOCH[1];

Abstract: The electrical properties of neuronal cells are shaped by their dendritic morphology and the composition and density of their synapses. Therefore, the mechanisms underlying dendritic morphogenesis have been extensively studied and have implicated several synaptic proteins to play a role in the regulation of neuronal branching. By analyzing primary rat neurons with reduced expression of RIM3γ and RIM4γ we recently identified the two short members of the RIM protein family as key regulators of neuronal arborization (Alvarez-Baron, Michel et al., J. Neurosci., 2013). The large multidomain RIMs, RIM1 and RIM2, are centrally involved in the organization of the presynaptic active zone. As a first step into gaining further insight into the γRIM-dependent processes mediating neurite outgrowth we performed a tandem-

affinity/Massspectrometry screen to identify γRIMs-specific interacting proteins. In this screen we found a cluster of proteins involved in the regulation of cytoskeleton and transport processes during neuronal development. For RIM3γ in particular, we uncovered proteins acting as Ca^{2+} sensors and nuclear transport receptors, suggesting an isoform specific function apart from neuronal outgrowth. The results of this study suggest a role for γRIMs in the transport processes delivering membrane and proteins to site of neuronal outgrowth.

Abstract: The vast majority of GABAergic neocortical interneurons arise from the medial (~70%) and caudal (~30%) ganglionic eminences (MGE and CGE) and the preoptic area, embryonic germinal zones in the ventral telencephalon. We have recently demonstrated that, although the majority of neuronal populations (pyramidal neurons and MGE-derived interneurons) integrate into the cortex in an inside-out manner based on their birthdate, CGE-derived interneurons selectively integrate into the superficial layers irrespective of their birthdate (Miyoshi et al., 2010, Miyoshi and Fishell 2011). We have also shown that CGE-derive interneurons consist of a characteristic assemblage of VIP-expressing bipolar or bitufted classes and RELN-expressing neurogliaform or dense plexus cells that are distinct from MGE-derived

populations.
In order to understand the genetic programs controlling the development of CGE-derived interneurons, we undertook a microarray expression screen analysis. We found that the homeodomain gene Prox1 is selectively expressed within CGE-derived interneuron precursors at the time they tangentially migrate within the cortex. Moreover, Prox1 expression is maintained throughout adulthood within CGE-derived populations. By using conditional genetic strategies, we demonstrate that Prox1 is essential for both embryonic tangential migration and postnatal maturation of CGE-derived interneurons.

Title: Erbb4 gene expression is required for normal cochlear nucleus morphology

Authors: *K. T. YEE;
Neurobio. and Anatom. Sci., Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: The cochlear nucleus (CN), as the first, and only direct, CNS synaptic locus to receive sound information from the cochlea, is a critical brain region for auditory processing. Elegant anatomical and physiological studies have provided detailed characterization of the morphology and response properties of cochlear nucleus neurons. Investigations of the molecular control of the auditory system has focused on stages of functional hearing, its onset as well as its decline and less emphasis has been placed on the roles of molecules during CN development. However, more recent studies have begun to examine the effects of early molecular control. The laboratory is interested in how early gene expression affects CN morphology as a model system for neuronal development.
The receptor tyrosine kinase, Erbb4, is important for developmental events in the CNS, including neuronal migration and differentiation. The laboratory has previously reported that *Erbb4* has a perinatal expression profile in the CN. Both the dorsal and ventral subdomains of the CN express *Erbb4* at E16.5. At birth, *Erbb4* mRNA is localized to the molecular and granule cell layers and

in cells within the deep regions of the dorsal and ventral regions of the nucleus. Reported here is that in Erbb4 loss-of-function mutant mice, general histological staining shows perturbed dorsal CN organization including altered organization of the core region of the ventral CN. More detailed examination labeling auditory nerve fiber terminals (Zhou et al., 2007) in this region with an antibody against vesicular glutamate transporter 1 (vGlut1; Millipore) reveals altered organization of the ventral (V) CN core. Volume measurements delineated by vGlut1 localization show no difference between all major CN subdomains with the exception of the VCN core. The homozygous null VCN core shows expansion compared to wild type VCN (t-test. P=0.0032).
These data show that developmental expression of the receptor tyrosine kinase *Erbb4* contributes to the normal anatomical organization of the CN. The difference in pattern of vGlut1 immunohistochemical localization in the VCN between *Erbb4* null and wild type mice suggests that Erbb4 may be important for structural organization in the VCN, including the positioning of afferents on glutamatergic neurons. Studies suggest that cells in the VCN core may be involved in rapid processing of monaural acoustic spectral patterns required for speech or detection of other natural sounds (Oertel et al. 2000); a role for *Erbb4* in development of the VCN also supports its contribution to these auditory processes.

Title: Length extension in FMRP KH-2 domain variable loop and neuronal differentiation

Authors: *L. A. HADDAD[1], F. J. VELLOSO[1], A. B. SAONA-MARÍN[1], J. C. CORREA[1], T. T. S. D. GOMES[2], H. ULRICH[3], L. R. G. BRITTO[4];

Abstract: Fragile Mental Retardation Protein (FMRP) is necessary for synapsis maturation and elimination in the mammalian cerebral cortex, hippocampus and cerebellum. It is encoded by the Fragile Mental Retardation 1 (FMR1) gene and displays three types of RNA-binding domains: two Agenet motifs, two K-homology (KH) domains and one RGG box. FMRP second KH

domain (KH-2) has been implicated in RNA-binding specifically to kissing complex structures in vitro, and ribosome association in vitro and in vivo. KH-2 domain in FMRP contains a long variable loop that may be submitted to further extension after exon-12 in-frame inclusion in Fmr1 mRNA. Its extended form is significantly expressed in the cerebral cortex of the rat in a critical period for synaptogenesis (postnatal day (P) zero through P42). Here, we present immunohistochemistry data of P12 encephalon with two antibodies that specifically discriminate between FMRP isoforms expressing Fmr1 exon 12 (FMRP+12ISO) or total FMRP. Consistent with Western blotting results, we disclose a significant expression of those isoforms in P12 cerebral cortex pyramidal neurons from frontal (including prefrontal cortex), temporal and occipital lobes, and cerebellum Purkinje and granule cells, but not in hippocampus, where total FMRP was observed mostly in the dentate gyrus. Conversely, the histological analysis of the telencephalon between embryonic days (E) 12 and 20 revealed low expression of FMRP+12ISO in the neuroepithelium of the paired telencephalic vesicles (E12 - E14). On the other hand, those isoforms distribute to the cortical plate on E20 though less intensely than total FMRP. In neurospheres primarily cultured in suspension from E14 rat telencephalic vesicle, FMRP+12ISO were barely identified. Their expression was increased upon in vitro neurosphere neuronal differentiation. Altogether, our data confirm the highest expression of FMRP+12ISO in cerebral cortex neurons within the first 30 days of the rat postnatal period, and indicate that Fmr1 exon-12 expression directly relates to neuronal differentiation in vivo and in vitro. The specific functional roles of FMRP+12ISO in the cerebral cortex of the rat remain to be determined in the critical postnatal developmental period when synapses are maturing.

Title: FoxD4 and neural development

Authors: *J. H. SHERMAN, M. FRALISH, B. KARPINSKI-OAKLEY, T. M. MAYNARD, S. A. MOODY, A. S. LAMANTIA;
The George Washington Univ., Washington, DC

Abstract: We evaluated the role of FoxD4, a forkhead family transcription factor, in the early steps of acquiring neural stem cell identity. In *Xenopus* embryos, FoxD4L1 serves as a key upstream regulator of numerous neural transcription factors and directs embryonic ectoderm towards a neural stem cell (NSC) lineage (Yan et al., 2009). The homologous gene in mice, FoxD4, is expressed in the embryonic central nervous system in a pattern similar to *Xenopus*. However, it is not known whether this transcription factor plays a similar role in promoting the development of NSCs in mammalian cells. We used a mouse ES to neural stem cell 7-day differentiation protocol to generate embryoid bodies (EB) and adherent neural stem cell cultures. FoxD4 expression appears after a neural differentiation step (RA treatment), which also causes a decline in pleuripotency markers (Nanog, Oct4, FoxD3). The peak expression of FoxD4 is concurrent with the expression of other markers of initial neural stem cell identity (Sox1, Isl1) and then declines as later neural progenitor (Nestin, N-Cad) and neuronal differentiation markers (neuronal beta-tubulin, neurofilament) emerge.. This time course of FoxD4 expression suggests that it is expressed in register with the transition between pleuripotent ES cells and initially committed neural stem cells. To evaluate the role of FoxD4 in this transition, we generated stable mESC lines that express siRNA "knockdown" constructs to diminish expression of *FoxD4*. We assessed differentiation of these "FoxD4-si" cells using the EBs for immature stem cell, neuronal precursor, and mature neuronal markers. We found that FoxD4-si cells retain ESC pluripotency. In early FoxD4-si EBs, undifferentiated cell markers (Oct4, FoxD3) remain expressed at high levels. In contrast, FoxD4-si derived EBs have decreased levels of neural differentiation markers (Zic1, N-cad) at slightly later stages in the differentiation protocol. Finally, FoxD4-si cells do not robustly express mature neuronal markers such as neurofilament and NCAM in adherent cultures that permit process outgrowth, nor is there extensive neurite growth from neurons derived from FoxD4-si cells. Together our results indicate that mammalian FoxD4 serves a parallel function to its *Xenopus* homologue as a key regulator of the transition from pluripotent ES cell to committed neural stem cell.

Title: TxnRd2 imbalance during critical stages in development results in changes in mitochondrial distribution and neurite outgrowth

Authors: *A. FERNANDEZ[1,2,3,4], T. MAYNARD[1,3,4], D. MEECHAN[1,3,4], B. OAKLEY[1,3,4], A. LAMANTIA[1,3,4];
[2]GW Inst. of Biomed. Sci., [3]Pharmacol. and Physiol., [4]George Washington Inst. for Neurosci., [1]The George Washington Univ., Washington, DC

Abstract: Mitochondrial redox imbalance and decreased antioxidant defense may accompany altered cortical circuit organization and function in patients with psychiatric disorders. Patients with 22q11 deletion syndrome (22q11DS) are at increased risk for these disorders; therefore, 22q11DS provides a model for studying their neurodevelopmental origins—including the role of aberrant mitochondrial function. About one quarter of the genes located in the 22q11DS minimal deleted region encode proteins that localize to mitochondria. Among these, mitochondrial thioredoxin reductase (TxnRd2) encodes a primary mitochondrial H_2O_2 scavenger, and is maximally expressed during cortical circuit differentiation. We have asked whether changes in dosage of TxnRd2 compromise neuronal differentiation. We hypothesized that diminished mitochondrial antioxidant defense due to TxnRd2 imbalance during late stages of neuronal development would result in aberrant neurite outgrowth. Primary cortical neuronal cultures from E16.5 mouse embryos were electroporated with farnesylated-GPF and mitochondrial-flagged TxnRd2 knock-down and overexpression plasmids. TxnRd2 depleted neurons were also treated with ROS scavengers to reestablish intracellular redox balance and link TxnRd2 scavenging activity to normal neurite outgrowth. Changes in neurite outgrowth and mitochondrial distribution were evaluated by 3D reconstruction and Sholl analysis. Depletion of TxnRd2 results in decreased neurite outgrowth and complexity, while overexpression leads to no significant changes. Treatment of TxnRd2 depleted neurons with ROS scavengers returned neurite outgrowth to control levels. Overexpression of TxnRd2 leads to abnormal mitochondrial morphology and distribution. Changes in neurite outgrowth and mitochondrial morphology upon TxnRd2 imbalance suggest a key role of TxnRd2 in neuronal differentiation. Reestablishment of processes outgrowth in TxnRd2 depleted neurons treated with ROS scavengers implies an inverse correlation between ROS accumulation and TxnRd2 activity. These data suggests antioxidant defense as key in neuronal functional capacity and provides insight into the role of redox imbalance in abnormal circuit formation in a wide range of behavioral disorders.

Title: Specificity of proneural basic helix-loop-helix transcription factors in retinal development

Authors: *T. J. KACZYNSKI[1,2,3], R. RUONALA[1,3], X. MU[1,2,4,3,5];
[2]Neurosci. Grad. Program, [3]Ctr. of Excellence in Bioinformatics and Life Sci., [4]Dept. of Ophthalmology/Ross Eye Inst., [5]SUNY Eye Inst., [1]SUNY Buffalo, Buffalo, NY

Abstract: Due to its accessibility and easy manipulation, the mammalian retina provides an ideal system for the study of neurodevelopment. Seven primary retinal cell types are produced during embryogenesis: rod and cone photoreceptors, horizontal, amacrine, and bipolar interneurons, retinal ganglion cells (RGCs), and the Müller glia. These cell types arise from a common pool of multipotent retinal progenitor cells (RPCs)
which differentiate into the various cell types primarily in response to the cell-autonomous inputs from transcription factors. The proneural transcription factors, which possess the basic helix-loop-helix (bHLH) DNA binding and dimerization motif, are critically involved in the genesis of retinal cell types from RPCs. All proneural factors possess a bHLH domain whose amino acid sequences are very similar to one another, and although each factor can bind identical DNA motifs, each plays a unique role in retinal development. The mechanism for the specificities of these transcription factors remains unknown.
For example, Math5 (also known as Atoh7) of this family is required for the production of RGCs, but another member, NeuroD, is required for amacrine cells and photoreceptors. To better understand which regions of Math5 are responsible for this specificity of function in the context of the retina, we performed domain-swap experiments between Math5 and NeuroD. Domain-swapped DNA constructs
were made possessing all or a portion of the bHLH region of one protein with the remaining flanking regions of the other. Math5 null mouse embryos, which lack the majority of RGCs, were electroporated with the constructs, and the retinas were examined for RGC formation. As expected, full-length Math5 could readily rescue RGC formation. In addition, the constructs containing the Math5 bHLH domain also rescued RGC formation, while constructs with the NeuroD bHLH domain failed to rescue RGC production even in cases where the flanking regions of Math5 were present. These results suggest that the bHLH domain of
the Math5 is a critical determinant of its specific function. More experimentation and analysis

are underway to further dissect the mechanism underlying the specificity of Math5 for the RGC fate.

Title: TRIM32-dependent microRNA activation is necessary for differentiation of neural stem cells

Authors: *S. NICKLAS[1,2], A.-L. HILLJE[1,2], I. MENZL[2], J. C. SCHWAMBORN[1,2]; [1]Luxembourg Ctr. For Systems Biomedicine, Esch-Belval, Luxembourg; [2]ZMBE, Inst. of Cell Biol., Münster, Germany

Abstract: During mouse embryonic brain development, neural stem cells undergo asymmetric cell divisions giving rise to one cell that maintains progenitor fate and one cell that differentiates into a neuron. Previously, we have shown that the cell fate determinant TRIM32 segregates asymmetrically to only one of these two daughter cells, where it suppresses self-renewal and induces neuronal differentiation by two mechanisms. On the one hand, the ubiquitin ligase TRIM32 ubiquitinates the transcription factor c-Myc, thereby targeting the protein for proteasomal degradation and inducing cell-cycle exit. Additionally, TRIM32 binds to the Argonaute-1 protein, which is part of the RNA-induced silencing complex. This interaction results in increased efficiency of post-transcriptional gene silencing through certain microRNAs. One of these microRNAs activated by TRIM32 is the stem cell regulator Let-7a, which is required and sufficient for neuronal differentiation. Furthermore, Let-7a has been shown to target c-Myc and to be in turn repressed by c-Myc. However, the exact mechanism of microRNA-

regulation by TRIM32 during neuronal differentiation has not been elucidated so far. Therefore, we are aiming at identifying functionally important components (protein and RNA) of the TRIM32/Argonaute complex that are important for the initiation of neuronal differentiation. In order to identify the protein components of this complex in neural stem cells we used a mass spectrometry approach. We were able to identify several new interaction partners which we analyzed in more detail with respect to their localization pattern in neural stem cells and their effect on microRNA activity in the presence and absence of TRIM32. Furthermore, via sequencing of TRIM32/Argonaute associated RNA, we aim at identifying microRNAs and mRNAs that are regulated by this complex. Finally, we want to analyze, how the newly identified protein components of the TRIM32/Argonaute complex regulate the activity of these associated mRNAs in a microRNA-dependent way. By this means we aim to unravel the molecular mechanism by which TRIM32 activates microRNAs to initiate neuronal differentiation in neural stem cells.

Title: Dissecting a spatio-temporal Rho GTPase signaling network regulating neuronal growth cone extension

Authors: *G. AZARIAS[1], M. BAGONIS[2], L. FUSCO[1], G. DANUSER[2], O. PERTZ[1];
[1]Dept. of Biomedicin, Basel, Switzerland; [2]Dept. of Cell Biol., Harvard Medical School, MA

Abstract: Neuronal outgrowth determines the brain connectivity and requires tight spatio-temporal signaling to the cytoskeleton through the Rho family GTPases. Classical biochemical and cell biological studies have suggested that RhoA activates acto-myosin contractility, whereas Rac1 And Cdc42 allow neurite extension. However, recent experiments using FRET-based biosensors have indicated that Rho GTPase activation occurs in transient micrometer-sized subcellular domains, that correlate with cell edge morphological dynamics on sub-minute time scales.
Using real-time fluorescence imaging of FRET-based Rho GTPase biosensors in intact living cells, we quantified the spatio-temporal Rho GTPase activation dynamics within neuronal

growth cones at micrometer length and second time scale. Contrary to the classical dogma, we observed that all three canonical Rho GTPases are activated in the advancing growth cone in specific micrometer-sized subcellular zones. RhoA was activated at the tip of filopodia, Cdc42 was activated throughout the filopodium, and Rac1 was activated in the growth cone body and at the basis of filopodia. Thus, all three canonical Rho GTPases might collaborate to fine tune growth cone cytoskeletal dynamics by placing specific effector pathways in time and space. To address this issue, we developed a novel computer vision approach that allows automated filopodium dynamics segmentation for quantitative analysis of our dynamic timelapse datasets. This will be used to measure how the activation of the three GTPases fluctuate during the filopodium protrusion and retraction cycles and produce a multiplexed model of the activation dynamics of the three Rho GTPases.
Thus, our multidisciplinary methodology will allow resolving a complex spatio-temporal signaling network at the time and length scale on which growth cone cytoskeleton operates.

Title: Osteopontin is expressed by the largest retinal ganglion cells (alpha RGCs) and causes RGC enlargement

Authors: *M. QIAO[1], X. DUAN[2], J. R. SANES[2];
[1]MCB, [2]Harvard Univ., Cambridge, MA

Abstract: The mammalian retina contains >20 different retinal ganglion cell (RGC) subtypes, each with distinct molecular, morphological and physiological properties. The largest are called alpha RGCs (aRGCs); in mice, Pang et al. (J. Neurosci, 2003) described three aRGCs subtypes, differing in dendritic morphology and visual responses. In the course of developing reagents to mark and manipulate retinal subtypes, we generated a mouse line in which Cre recombinase is inserted into the KCNG4 locus. This line marks subsets of RGCs with large somas and dendritic fields, as well as some bipolar cells. Labeled RGCs were present throughout the retina and were neurofilament-positive, suggesting they were aRGCs. Single cell labeling showed that the

KCNG-positive RGCs comprise three subtypes with distinct dendritic laminar restrictions. Physiological analysis followed by dye-filling revealed that these three subtypes correspond to the ON sustained, OFF sustained and OFF transient aRGCs described by Pang et al. Furthermore, analysis of double-transgenic mice demonstrated that the KCNG4 RGCs include all RGCs labeled in the CB2-GFP and W7-YFP lines, previously shown to label OFF aRGC subtypes (Huberman et al. 2008; Kim et al. 2010). Thus, the RGCs labeled in the KCNG4 line include nearly all and nearly only aRGCs.
We then used these lines for molecular analysis, and found that all aRGCs labeled in all three lines (KCNG4, CB2 and W7) express an O-glycosylated phosphoprotein, osteopontin (OPN), and that all OPN-positive RGCs are aRGCs. Developmental analysis shows that expression of OPN increases during the postnatal interval when somata of aRGCs become larger than those of other RGCs. Knowing that osteopontin regulates growth in nonneuronal cells (Rangaswami et al. 2006), we have begun to test the idea that OPN promotes RGC growth. We used an adeno-associated virus (AAV) to express OPN in non-aRGCs, and found that it leads to an increase in their soma size. These results suggests the possibility that OPN contributes to making aRGCs the largest RGCs. (Supported by NIH.)

Title: The ubiquitin ligase Praja1 reduces NRAGE expression and inhibits neuronal differentiation of PC12 cells

Authors: *J. TEUBER[1], B. MUELLER[1,2], R. FUKABORI[1], D. LANG[1], A. ALBRECHT[1], O. STORK[1];

Abstract: Evidence suggests that regulated ubiquitination of proteins plays a critical role in the development and plasticity of the central nervous system. We have previously identified the ubiquitin ligase Praja1 as a gene product induced during fear memory consolidation. However, the neuronal function of this enzyme still needs to be clarified. Hence, we investigated its involvement in the nerve growth factor (NGF)-induced differentiation of rat pheochromocytoma (PC12) cells. Praja1 has been shown to precipitate the neurotrophin receptor interacting MAGE homologue (NRAGE) in a GST pull-down and to occur in a complex with NRAGE and Msx2. NRAGE is a mediator of p75NTR-dependent NGF signalling and has been identified as a potent modulator of apoptosis. Aside from this, contradictory effects on neurite outgrowth in PC12 have been described. Our findings show that Praja1 co-localizes with cytoskeleton components and decreases the pro-apoptotic effects of NRAGE. Furthermore, we observed an enhanced expression of Praja1 after 3 days of NGF treatment and a suppression of neurite formation upon Praja1 overexpression in stably transfected PC12 cell lines, which was associated with a proteasome-dependent reduction of NRAGE levels. Our data thus suggest that Praja1, through ubiquitination and degradation of NRAGE, inhibits neuronal differentiation. The two murine isoforms, Praja1.1 and Praja1.2, appear to be functionally homologous in this respect.

Abstract: miRNAs are small non-coding RNAs that are important in post-transcriptional regulation of gene expression. The functions of miRNAs in neurons are just beginning to emerge, however there are indications that miRNAs drive neuronal differentiation and morphogenesis through specific expression patterns. Understanding these changes in the miRNAome during neurite outgrowth would lead to new insights into the molecular processes involved and might provide new therapeutical targets to treat diseases of the central nervous system. We employed massive parallel sequencing and present the complete and quantitative miRNAome of murine primary midbrain neurons at different time points of neuronal maturation and neurite outgrowth. 848 out of 1410 murine miRNAs were detected. Differential expression analysis revealed that the major changes in miRNA expression occur between day 1 and day 5 in vitro. 163 miRNAs were significantly regulated and 47 of these showed a more than 4-fold change in expression levels. Target prediction and functional annotation of these predicted target genes were performed to identify miRNAs involved in neurite outgrowth. As the midbrain is central target of neurodegenerative diseases such as Parkinson's disease and has limited regenerative capacities, detailed knowledge about miRNA-mediated regulation of molecular processes involved in neurite outgrowth may be useful for the identification of future therapeutic targets in degenerative CNS diseases.

Title: TRIM32 dependent transcription in adult neural progenitors regulates neuronal differentiation and olfactory learning

Authors: *M. A. PAVLOU[1,2], A.-L. HILLJE[1,2], E. BECKMANN[3], M. WORLITZER[2], L. BAHNASSAWY[1], L. LEWEJOHANN[4], T. PALM[2], J. SCHWAMBORN[1,2];

Abstract: In the adult brain, neurogenesis is restricted to the subventricular zone (SVZ) of the lateral ventricles and the dentate gyrus of the hippocampus. Adult neural stem cells in the subventricular zone continuously generate new neurons for the olfactory bulb. As a defining feature of all stem cells, also these adult NSCs have the ability to simultaneously self-renew and generate more fate committed daughter cells. Astrocytes (also known as type B cells) localized in the SVZ, function as primary progenitors that give rise to fast dividing transit amplifying cells (type C cells) which then differentiate into neuroblasts (type A cells). Neuroblasts leave the SVZ and migrate through the rostral migratory stream (RMS) to their final destination the olfactory bulb, where they differentiate into neurons. This fate commitment is regulated by cell fate determining proteins. The TRIM-NHL protein family has an evolutionary conserved function in neuronal cell fate specification. In mammals the protein TRIM32 is so far the only asymmetrically segregating neuronal fate inducing determinant. Here, we show that the cell fate determinant TRIM32 is upregulated during maturation of adult neural stem cells into olfactory bulb neurons. This upregulation is accompanied by neural progenitor cell divisions which show an asymmetric distribution of TRIM32 during mitosis. We further demonstrate that TRIM32 is necessary and sufficient for neuronal differentiation in adult neural stem cells, through overexpression and knockdown experiments in vivo using stereotactic injections. Interestingly, TRIM32-deficency induced overproduction of new olfactory bulb neurons, leads to a clear impairment in olfactory learning processes. Thus, we provide evidences for a function of TRIM32 for neuronal differentiation of adult neuroblasts and we correlate the cell fate determinant dependent activity of adult neurogenesis with complex learning behavior.

Title: Contributions of bHLH transcription factors to dopaminergic and neuroendocrine differentiation in the zebrafish ventral diencephalic Orthopedia expressing precursor domain

Authors: *M. RATH, W. DRIEVER;
Developmental Biol., Univ. of Freiburg, Freiburg, Germany

Abstract: During neural development, patterning mechanisms specify regional identities in a coordinated fashion in the vertebrate brain. Expression domains of specific transcription factors then drive differentiation of one or several different neuronal identities in these anatomical domains. The Orthopedia (Otp) transcription factor defines a domain within the ventral diencephalon, including preoptic and hypothalamic territories, where dopaminergic A11-type neurons as well as neuroendocrine and other neuronal cell types develop. How specific neuronal identities are established within the Otp expressing regions is not well understood. In principle, more refined regional patterning mechanisms, differentially migrating precursor populations, but also proneural transcription factors driving lineage decisions, may contribute to neuronal cell type diversity.
We use the zebrafish model to investigate dopaminergic (DA) and neuroendocrine neuron differentiation within the Otp-expressing precursor region. In this region, next to DA, corticotrophin-releasing hormone (CRH), isotocin (ITNP) and vasotocin (VSNP) neurons form. The transcription factors Otp, Aryl-hydrocarbon receptor nuclear translocator 2 (Arnt2), and Single-minded 1 (Sim1) act together during specification of these neurons (Ryu et al. 2007, Löhr et al. 2009). Loss-of-function for each of these transcription factors reduces both DA and neurosecretory cell types. The mechanisms downstream of Otp that segregate DA from the other lineages are currently unknown. Given that proneural bHLH transcription factors have previously been shown to mediate other lineage decisions in the hindbrain and spinal cord, we investigated whether the proneural bHLH factors Ngn1, Olig2, or Ascl1a, which have previously been shown to be involved in DA development (Jeong et al., 2006; Brodowsky et al., 2009; Liu et al., 2011), may contribute to lineage decisions in the Otp domain. We also included in our analysis additional bHLH factors identified by transcriptional profiling. Further, DA neurons, but also CRH neurons, of the hypothalamus are characterized by double neurotransmitter phenotypes, which we analyze to determine shared and unique features of transcriptional control of the complex neurotransmitter identity of these neurons.

Sci., Tokyo, Japan

Abstract: DNA methylation is known to influence a variety of biological aspects such as development, cell differentiation and genomic reprogramming. In mammals, DNA methylation patterns are established and maintained by DNA methyltransferases, DNMT1, -3A, and -3B. During cortical development, neurons and glial cells (astrocytes and oligodendrocytes) are generated from common multipotent neural stem cells (NSCs) in a temporal order, in which neurons are generated first at mid-gestation, followed by glial cells at late-gestation. During mid-gestation, when neuronal differentiation is dominant, DNMT1 plays an essential role in the inhibition of precocious astrocyte differentiation by maintaining DNA methylation of astrocytic gene promoters. Previously, we observed that DNMT1 expression was not only confined to mid-gestation, but expressed by NSCs in all development stages. The prevalence of DNMT1 expression suggests a novel role of DNMT1 regulating cortical development. Toward the functional analysis of DNMT1 in late-gestational neural stem cell (lg-NSC), we found that NSCs overexpresing DNMT1 were stalled at VZ/SVZ, instead of following the differentiation and migration route. Targeted DNMT1 knock out in lg-NSC led to increased cell cycle exit, resulting in diminished stem cell pool. Furthermore, shRNA-mediated DNMT1 knock down in cultured lg-NSCs resulted in increased neuronal differentiation, while the overexpression of DNMT1 inhibited neuronal differentiation of lg-NSCs. Interestingly, overexpression of mutant DNMT1 lacking methylation activity also reduced neuronal differentiation of lg-NSCs. These results suggest DNMT1 as a neuronal differentiation repressor of NSCs during late-gestation and this repression occurs in a DNA methylation-independent manner. To explore the molecular mechanisms, we will be seeking to identify the target genes and interacting proteins of DNMT1 *via* the gene expression profiling and proteomic analysis, respectively.

Title: The role of N-cadherin cytoplasmic terminal fragment in modulating beta-catenin activity during brain development

Authors: *M.-H. WEN[1,2], M.-P. WANG[1], C.-Y. TAI[1];
[1]Inst. of Mol. Biology, Academia Sinica, Nankang, Taipei, Taiwan; [2]Grad. Inst. of Life Science, Natl. Def. Med. Ctr., Taipei, Taiwan

Abstract:
N-cadherin works together with its intracellular binding partner beta-catenin in neuronal migration, lamination and synaptic connections. On the other hand, beta-catenin is also a key mediator for Wnt signaling, which drives the proliferation of neuroprogenitor cells in early brain development. However, the role of N-cadherin in this Wnt/beta-catenin mediated event remains unclear. Recent evidence has demonstrated that the cytosolic-terminal fragment (CTF) of N-cadherin can be released from membrane upon gamma-secretase mediated proteolysis. Therefore we speculate that the released N-cadherin CTF may modulate Wnt/beta-catenin functions. Here we show that the protein level of N-cadherin CTF is higher in embryonic than in adult brains. This developmental switch of N-cadherin CTF level correlates with the gamma-secretase activity. Overexpression of CTF facilitates nuclear translocation of beta-catenin both in heterologous cells and cultured neurons. However the transcriptional activity of beta-catenin is suppressed, despite the elevated protein level inside the nucleus. Together, our results suggest that N-cadherin may negatively regulate Wnt/beta-catenin signaling via proteolytic regulation during brain development.

Title: Evidence for the involvement of DNA polymerase β in the regulation of neuronal energy metabolism

Authors: *M. M. MISIAK[1,2], P. SYKORA[1], D. CROTEAU[1], M. P. MATTSON[2], V. A. BOHR[1];
[1]Lab. of Mol. Gerontology, NIH/National Inst. On Aging, Baltimore, MD; [2]Lab. of Neurosciences, NIH/National Inst. on Aging, Baltimore, MD

Abstract: DNA repair is essential for brain development, and impaired DNA repair is implicated in developmental and adult neurological disorders. As the primary DNA polymerase involved in base excision repair (BER), DNA polymerase β (Pol β) is critical for preventing mutations, and is also required for proper neurogenesis during brain development. In the absence of Polβ, neurons in the brains of mice undergo massive perinatal apoptosis. However, the cause of this neuronal apoptosis is unknown. Interestingly, even when apoptosis is prevented by the concomitant deficiency of the pro-apoptotic factor p53, mice still display major brain abnormalities, suggesting that Polβ is required for normal neural progenitor cell differentiation. Additionally, astrocytes are important for maintaining and supporting neuronal functions and metabolism, such that when astrocytes are missing or their function is impaired, neurons cannot function properly and may die. Therefore, we postulate that neuronal apoptosis and embryonic death shortly after birth in Polß-/- mice might be related to impaired proliferation and/or differentiation of astrocytes, and to an associated metabolic impairment. To test this hypothesis, we cultured cortical cell neurospheres from wild type (WT) and Polβ-/- embryos and differentiated those progenitor cells into neurons or astrocytes. Polβ-/- neurons showed normal morphology and were able to grow neurites. Cultured Polβ-/- astrocytes grew significantly slower than WT astrocytes, suggesting a proliferation defect. Analysis of mitochondrial metabolism in neurons revealed that Polβ-/- neurons exhibit higher basal oxygen consumption, lower reserve capacity, and are unable to switch to glycolysis when oxidative phosphorylation is inhibited. This metabolic abnormality in Polβ-/- neurons may render them highly dependent on astrocytes for lactate production. We are currently performing studies aimed at establishing the molecular mechanisms by which deficiency in a DNA repair enzyme adversely affects neuronal energy metabolism and vulnerability to synaptic dysfunction and degeneration.

Title: Molecular microdomains of germinative epithelium in mouse cerebellum generate different clusters of cerebellar cortical neurons

Authors: *R. GARCIA-LOPEZ[1], A. POMBERO[1], J. HOHMANN[2], C. THOMPSON[2], K. GLATTFELDER[2], V. MENON[2], W. WAKEMAN[2], M. HAWRYLYCZ[2], C. DANG[2], S. MARTINEZ[1];
[1]Inst. Neurociencias, San Juan De Alicante, Spain; [2]Allen Inst. for Brain Science,, Seattle, WA

Abstract: The cerebellum is an attractive brain region due to its sophisticated circuitry, high degree of modifiability combined with unique operational mechanisms, and the growing awareness of its multiple roles in animal motor and cognitive behavior. The mature cerebellum is a highly organized structure partitioned into lobules and lamella along the anterior-posterior (A-P) axis, and into striped molecular domains along the medial-lateral (M-L) axis. We have studied the expression patterns of 67 genes (expressed in E13.5 and E15.5 mouse cerebellar ventricular epithelium) at E15.5, E18.5 and postnatal (P4, P14, P28) stages using the Allen Developing Mouse Brain Atlas (www.brain-map.org/). Then we generated combinatorial maps of regional expression patterns in order to: 1) establish molecular references to detect morphogenetic field limits in developing cerebellum; 2) analyze maintenance of the ventricular molecular labeling in cellular migratory streams; 3) describe specific molecular markers for neuroepithelial presumptive regions and 4) identify potential regulatory genes underlying neural differentiation in cerebellar cortex. The quality and the resolution of the data revealed previously undetected molecular microdomains of germinative epithelium in mouse cerebellum that can be related to the complex origin of cerebellar plate, from mesencephalic, isthmic and rhombomere1 progenitors.

Title: Making the match: How are postsynaptic receptors paired with presynaptic transmitters?

Authors: *D. R. HAMMOND-WEINBERGER[1], N. C. SPITZER[1,2];
[1]Neurobio. Section, Div. of Biol. Sci., UCSD, La Jolla, CA; [2]Kavli Inst. for Brain and Mind, La Jolla, CA

Abstract: Electrical activity participates in the specification of neurotransmitters in different classes of neurons. At the developing Xenopus neuromuscular junction, motor neurons normally express the neurotransmitter acetylcholine (ACh) paired with cognate ACh receptors on muscle. In addition to ACh receptors, developing muscle cells express non-cholinergic receptors before innervation that are subsequently eliminated by an unknown mechanism. Changes in electrical activity of these immature motor neurons during a critical period specify a homeostatic shift to non-cholinergic neurons and the retention of matching, non-cholinergic receptors from the initially diverse receptor pool, identified anatomically and functionally. Enhanced activity results in a switch from excitatory ACh to inhibitory GABAergic or glycinergic neuronal phenotypes and retention of GABA or glycine receptors. Reduced activity results in a switch from ACh to combinations of cholinergic and glutamatergic phenotypes, with the retention of both ACh and glutamate receptors. The mechanism of receptor matching remains elusive.
We cultured neurons and muscle cells in the presence or absence of extracellular Ca2+ to alter neuronal activity and sustain or increase the number of glutamatergic neurons. Although the 0-Ca2+ medium failed to yield an immunocytochemically detectable increase in expression of ionotropic glutamate receptors on either innervated or uninnervated muscle cells, a greater number of cells were sensitive to exogenous glutamate, as assayed with the fluorescent Ca2+ indicator Fluo-4AM. The increase in glutamate sensitivity was blocked when NBQX and AP5 were added to the culture medium to block ionotropic glutamate receptors and washed out before testing glutamate sensitivity. Thus, changes in receptor function appear to precede changes in anatomically identified receptor populations, and receptor activation is necessary for the increase in sensitivity. We are determining whether receptor activation is also sufficient to increase the glutamate sensitivity in cultures of muscle cells without neurons and are testing the roles of Ca2+-dependent kinases in silencing the glutamatergic receptor population in developing muscle

cells. Activation of glutamate receptors may shift the balance of intracellular Ca2+ signaling and affect the maintenance of appropriate receptors and elimination of inappropriate classes as a homeostatic mechanism to maintain a functional circuit. This research is expected to be pertinent to understanding the dysregulation of transmitter receptors associated with neurological and psychiatric disorders. Supported by NIH grants.

Title: Regulation of p53 during neuronal differentiation

Authors: *S. GHASSEMIFAR, S. MENDRYSA;
Basic Med. sciences, Purdue Univ., West Lafayette, IN

Abstract: During nervous system development, failure of differentiation of neural stem cells (NSCs) and their derivative cells to mature neurons allow these cells to continue proliferating and is speculated to contribute to the development of embryonal brain tumors including medulloblastoma (MB), the most common malignant brain tumor in children. Although current treatments are capable of killing these tumors, they are also toxic to normal cells leading to devastating side effects especially in infants whose nervous system is still developing. A potentially less toxic approach to treat these tumors is to promote cell differentiation. The p53 tumor suppressor protein has been implicated in the regulation of neuronal differentiation in addition to having important roles in apoptosis, proliferation and self-renewal. Given the fact that p53 is not mutated in most embryonal brain tumors, development of strategies that specifically activates p53 prodifferentiation function is predicted to benefit the patients with these tumors. In this study, we investigated how p53 function is regulated during neuronal differentiation by employing the human embryonal teratocarcinoma NT2 cell line in which neuronal differentiation can be induced by retinoic acid treatment. We found that p53 is activated in differentiating NT2 cells concomitant with a decrease in level of MDM2, the key inhibitor of p53. Our data support a model in which proteasomal degradation of MDM2 is enhanced upon neuronal differentiation.

Consistent with our model, we observed a change in the levels of several regulators of MDM2 stability including USP2a, HAUSP and PCAF. Our findings identify MDM2 as a potential target for differentiation therapy of the embryonic brain tumors in which p53 is wild type.

Title: Regulation of retinal ganglion cell fate specification and differentiation by miR-23a and miR-374 during retinal development

Authors: *A. VAZHANTHODI[1], S. SREEKANTH[2], M. S. DIVYA[1], T. S. DIVYA[1], S. B. DHANESH[1], C. SUBASHINI[1], V. ANI DAS[2], J. JAMES[1];
[2]Mol. Neurobio. Lab., [1]RAJIV GANDHI CENTRE FOR BIOTECHNOLOGY, THIRUVANANTHAPURAM, India

Abstract: Retinal ganglion cells (RGCs) are one of the specialised neurons among the seven cell types in the retina that transmit the visual signals to the brain. The timing of RGC genesis, the first formed retinal cell type, from its progenitors and its maturation into a functional neuron is an important aspect that still remains as a piece of puzzle. The development of RGCs are controlled by various extrinsic factors such as Shh, FGF2, etc. and intrinsic regulators that include transcription factors such as Ath5, Brn3b, Isl1, Wt1, etc. Brn3b or Pou4f2, a POU domain binding transcription factor, has been found to play a major role in RGC survival and axonal guidance. The question that we asked next was regarding the factors that regulate Brn3b expression and how it regulates the RGC development. Recent studies have shown microRNAs to be involved in regulating the expression of various genes post transcriptionally thereby regulating their translation. For this we carried out *in silico* screening for microRNAs that target Brn3b and narrowed down to miR-23a and miR-374 for further analysis, since these two were

picked up by multiple programs. Temporal expression analyses of these miRNAs demonstrate that their expressions are well orchestrated to regulate the expression of Brn3b pattern during mouse retinal development. We further analyzed its role during retinal development and found that miR-23a and miR-374 by itself could not significantly regulate the expression of Brn3b but when expressed together could precisely down regulate Brn3b and also affect the patterning of the retina. Further we corroborated these finding in E14 retinal explants after *ex vivo* electroporation where we found altered patterning in Ganglion cell layer with loss of Brn3b expressing cells upon combined expression of miR-23a and miR-374. These finding highlight a post transcriptional regulatory mechanism of Brn3b, an intrinsic factor involved in RGC differentiation, survival and axonal growth during retinal development. In view of these finding we are currently pursuing the role of these miRNA in the maturation and axonal guidance of RGCs.

Title: Transcription factor network specifying inhibitory and excitatory neurons in the dorsal spinal cord

Authors: *M. D. BORROMEO[1], D. MEREDITH[1], D. S. CASTRO[2], K. C. TUNG[1], F. GUILLEMOT[3], J. E. JOHNSON[1];
[1]Neurosci., UT Southwestern Med. Ctr., Dallas, TX; [2]Inst. Gulbenkian de Ciência, Oeiras, Portugal; [3]MRC Natl. Inst. for Med. Res., London, United Kingdom

Abstract: The proper formation of the central nervous system (CNS) requires the proper balance of excitatory and inhibitory neurons; disruption of this balance may cause neurological disorders, such as somatosenory disorders and epilepsy. Neural basic helix-loop-helix (bHLH) transcription factors play a crucial role in generating the correct number and sub-types of neurons in the dorsal spinal cord. Little is known about the transcriptional targets of these regulators particularly as it relates to their neuronal subtype specification functions. We searched for potential direct downstream transcriptional targets of two neural bHLH factors Ascl1 and Ptf1a during the

neurogenic stage of the developing mouse spinal cord by using chromatin immunoprecipitation coupled to massive parallel sequencing (ChIP-Seq), and by coupling transcriptome analysis (mRNA-Seq) from isolated Ascl1 and Ptf1a lineage cells. We show Ascl1 and Ptf1a not only regulate genes important for neuronal differentiation, but also genes that are important for specification of the excitatory and inhibitory neurons in the dorsal spinal cord. Ascl1 directly activates a glutamatergic specification program that includes specific transcription factors Tlx1/3 and Lmx1b. In contrast, Ptf1a directly activates a GABAergic specification program that includes specific transcription factors Lhx1, Lhx5, and Pax2; and components of the GABA biosynthesis and transport pathway, such as Gad1 and Slc32a1. Current analyses are directed towards distinguishing how Ascl1 and Ptf1a select their specific targets in the developing spinal cord.

Title: Selective expression and developmental impact of the Met receptor tyrosine kinase in B6 subgroup of serotonin neurons

Authors: *H.-H. WU[1], S. CHOI[1], K. KIKUMA[2], E. DENERIS[3], P. LEVITT[1,2];
[1]Cell and Neurobio., [2]Neurosci. Grad. Program, USC, Los Angeles, CA; [3]Dept. of Neurosci., Case Western Reserve Univ., Cleveland, OH

Abstract: The autism risk gene, Met receptor tyrosine kinase, and its ligand, HGF have been implicated in a wide variety of roles during nervous system development. *Met* expression and its role in mouse forebrain development have been under extensive investigation. However, the expression patterns and function of *Met* in the developing brainstem is less well understood. In situ mapping of *Met* transcript revealed positive neurons in a highly restricted domain of the developing dorsal raphe (DR) up to birth. Immunocytochemical co-localization revealed that a subset of serotonergic raphe neurons is MET^+. Detailed mapping in serial coronal sections at embryonic day (E)16 and sagittal sections from E16 to postnatal day (P)4 revealed that MET is expressed almost exclusively in the caudal part of DR as a paired nucleus situated just below the aqueduct, a region corresponding to the B6 subgroup of the raphe. Double immunostaining on

sections from *Pet-1* knockout mice (*Pet-1KO*) was performed. Remarkably, there was no detectable MET protein expression in the DR of homozygous *Pet-1* null mice, even though residual 5-HT^{+} neurons were observed. These data suggest that MET expression in B6 subgroup of DR 5-HT neurons is Pet-1 dependent. Initial analyses of deleting *Met* with the *Pet-1*^{Cre} line suggest that MET signaling may be important for normal B6 neuron assembly. Finally, a bioinformatics analysis using several public databases generated a listing of B6-enriched genes. Gene expression of candidates is being evaluated in WT, *Pet-1KO*, and *Pet-1*^{Cre} x *Met*^{fx} mice.

Title: Neurod1/2/6 regulate hippocampal pyramidal neuron differentiation and survival

Authors: *O. GRISHINA[1], I. BORMUTH[1], K. YAN[1], T. YONEMASU[2], S. GOEBBELS[2], K. A. NAVE[2], M. H. SCHWAB[2], V. TARABYKIN[1];

Abstract: The hippocampus is probably the best studied part of the cerebral cortex. It is essential for learning and memory and accepted as model system for cortical information processing. The hippocampal formation is comprised of pyramidal neurons (cornu ammonis), granule cells (dentate gyrus), and interneurons. During embryonic development, neuroepithelial cells in the ventricular zone give rise to neuronal precursors which migrate and differentiate into functional granule and pyramidal neurons. The molecular mechanisms of these differentiation processes are still poorly understood.
Granule cell differentiation has been shown to dependent on the bHLH transcription factor Neurod1. In Neurod1 deficient mice, granule neurons undergo apoptosis resulting in agenesis of

the dentate gyrus. The generation of pyramidal neurons is not affected by inactivation of Neurod1 alone. These cells express two related factors, Neurod2 (NDRF) and Neurod6 (NEX), which serve redundant functionality.
We studied Neurod1/2/6 triple mutant mice and found hippocampal pyramidal neurons to stop differentiation and undergo apoptosis in a very similar manner. The mitotic activity in the ventricular zone of Neurod1/2/6 triple mutants is not reduced. Immature pyramidal neurons migrate radially and become apoptotic shortly after futile activation of the endogenous Neurod6 promoter. The generation of interneurons and glial cells is not affected in Neurod1/2/6 triple mutant mice. Intrestingly, pyramidal neurons can survive and differentiate in dissociated neuron cultures but not organotypic slice cultures prepared from Neurod1/2/6 mutant hippocampal tissue. This argues for a cell extrinsic effect and enables us to study the underlying mechanisms on a cellular level.

Title: Nato3 induces the expression of key DA neuron markers in a regionally and temporally specific manner within the developing CNS

Authors: J. L. STRAIGHT[1], D. PETERSON[1], *M. K. TAYLOR[2];
[1]Cell and Mol. Biol., Grand Valley State Univ., Allendale, MI; [2]Biomed. Sci., Grand Valley State Univ., Grand Rapids, MI

Abstract: In the developing stages of the central nervous system (CNS), neural stem cells gradually adopt specific cell fates and differentiate accordingly. The floor plate of the developing midbrain gives rise to dopaminergic (DA) neurons, an important class of neurons involved in Parkinson's disease. Better understanding of the mechanisms by which DA neurons are created is of great interest and would accelerate promising applications such as cell replacement therapies. Nato3, a basic helix-loop-helix transcription factor, is expressed in the floor plate

region of the midbrain during development. In vitro studies suggest that Nato3 overexpression is sufficient to promote floor plate and DA neuron marker expression, whereas in vivo studies suggest that Nato3 is not. Here, we show that overexpression of Nato3 in the developing chick produces a regionally and temporally dependent increase in DA neuron markers Nurr1 (an immature DA neuron marker) and tyrosine hydroxylase (TH) (a mature DA neuron marker) within the ventral midbrain. In-ovo electroporation was used for transfection, and Nato3 overexpression was monitored using a bicistronic EGFP reporter expression vector. The observed effects were characterized by quantitative PCR and immunohistochemistry. The regionally specific action of Nato3 on DA neuron markers suggests that it is regulated by an unknown mechanism that functions early in development within the ventral midbrain. These data provide new insight into the action of Nato3 on DA neuron marker expression in vivo and help to better characterize the role that Nato3 plays in DA neurogenesis.

Title: *In vitro* generation of human cortical interneurons for transcriptome analysis

Authors: *J. L. CLOSE[1], S. YAO[2], S. ANDERSON[4], R. DOLMETSCH[3];
[2]Structured Sci., [3]Mol. Networks, [1]Allen Inst. For Brain Sci., Seattle, WA; [4]Psychiatry, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Malfunction or loss of GABAergic interneurons has been implicated in multiple human neurodevelopmental and psychiatric disorders, including schizophrenia, autism spectrum disorders and epilepsy. However, little is known about the molecular events that characterize human interneuron differentiation. Here we have established a protocol to efficiently generate human GABAergic cortical interneurons in vitro from human embryonic stem cells and induced pluripotent stem cells. We have characterized the gene expression profile of these cells over time to determine the key molecular events during human interneuron differentiation and find that in vitro-generated interneurons express many of the transcription factors found to be crucial for interneuron differentiation in mouse. Our approach will allow us to identify novel regulators of interneuron differentiation and determine gene expression changes in iPSCs derived from disease patients.

Title: Toll like receptor 5 regulates adult neurogenesis through modulating neural stem cell proliferation and differentiation in hippocampus

Authors: S. CHOI, K. SEONG, M. KIM, J. YANG, M. PARK, J. JUNG, *W.-J. KIM;
Med. Res. Ctr. for Biomineralization Disorders, Med. Res. Ctr. For Biomineralization Disordersschool of Dentistry, Chon, Gwangju City, Korea, Republic of

Abstract: Recent reports have showed that several TLR family members were expressed in mouse embryonic/ adult stem cells, suggesting that these may play a role in stem cell activities. To address the possibility that TLR5 plays a functional role in neural stem/progenitor cell proliferation and differentiation from adult mouse, we checked the expressional pattern of TLR5 with SOX2 (stem cell marker) and DCX (new born neuronal marker). TLR5-positive cells were co-localized with SOX2 and DCX in hippocampal dentate gyrus of adult mouse. To verify a role of TLR5 on neural stem/progenitor cell (NSPC) proliferation, we administrated BrdU in TLR5 KO mouse and wild type mouse. TLR5 KO mouse demonstrated a marked increment in BrdU-positive cells in the hippocampal dentate gyrus 2.5 hrs after single injection compared with wild type mouse. To elucidate effect of TLR5 on neural differentiation, we checked DCX/BrdU or NeuN/BrdU double positive cells. TLR5 KO mouse showed a decrease in DCX/BrdU-double labeled cells and NeuN/BrdU-double labeled cells relative to wild type mouse. When we administrated Flagellin known as TLR5 specific agonist in mouse, BrdU-positive cells are transiently reduced and also BrdU/DCX-positive cells were increased in hippocampal dentate gyrus. Taken together, our data suggest that TLR5 plays a crucial role in adult neurogenesis from the hippocampal dentate gyrus in mouse.

Title: Differential regulation of histaminergic neurons by dopaminergic signaling pathways in zebrafish larval brains

Authors: *Y.-C. CHEN, P. PANULA;
Univ. of Helsinki, Helsinki, Finland

Abstract: Parkinson's disease with severe brain damage in the nigrostriatal dopaminergic system is also characterized by increased histamine level and histaminergic innervation in the substantia nigra. However, the mechanism of this pathological alteration is unknown. Dopamine interacts with five dopamine receptors. The D1-like receptors comprise D1 and D5 receptors coupled to stimulatory subsets of G proteins to activate adenylyl cyclase. The D2-like receptors including D2, D3, and D4 receptor are coupled to inhibitory G proteins, which inhibit cAMP synthesis. To investigate which subtype of dopamine receptors may modulate the histaminergic neuron development, 1-dpf fish embryos were treated with L-dopa (dopamine precursor), SKF38393 (D1-like receptor agonist), quinpirole (D2-like receptor agonist) and haloperidol (D2-like receptor antagonist) until 5 dpf. The drug effect on the histaminergic neurons was studied by counting histamine-ir and hdc expressing cells. We found that in L-dopa, quinpirole and SKF38393 treated groups the number of histaminergic cells in the caudal hypothalamus was significantly decreased, whereas the number of TH1-ir cells was increased in the diencephalic region including TH1 cell groups 8 to 13 compared with the sham treatment. Haloperidol treatment did not alter the number of the histaminergic neurons. Furthermore, the quinpirole administration restored the decrease of histaminergic neurons in th1-deficient fish brains. On the other hand, L-dopa and quinpirole treatments neutralised the increase of histaminergic neurons in th2-deficient brains. We also found that overexpression of Wnt antagonist dickkop 1 increased dopaminergic neurons in the diencephalon whereas the histaminergic neurons were significantly reduced. These results indicate that the overactive dopamine system has a negative effect on the histaminergic neuron development; in contrast, lack of dopamine raises the histaminergic neuron numbers, suggesting that dopamine is involved in the regulation of the histaminergic system during zebrafish development.

Title: Study of the basal forebrain in LIS1 mutant mouse

Authors: *A. POMBERO[1], R. GARCIA-LOPEZ[1], O. REINER[2], R. TABARES-SEISDEDOS[3], S. MARTINEZ[1];
[1]Inst. De Neurociencias, San Juan De Alicante, Spain; [2]2-Department of Mol. Genet. Weizmann Inst., Rehovot, Israel; [3]UVEG-UMH-CIBERSAM, Dept. of Medicine, Univ. of Valencia., Valencia, Spain

Abstract: *LIS1* is one of principal genes related with Type I lissencephaly, a severe human brain malformation characterized by an abnormal neuronal migration in the cortex and underlaying predisposition to develop mental disorders. The role of this gene has been studied using the *Lis1/sLis1* murine model, which has deleted the first coding exon from the *Lis1* gene. Homozygous mice are not viable but heterozygous have shown abnormal neuronal morphology and cortical dysplasia, hippocampal abnormalities and enhanced excitability. *Lis1/sLis1* embryos also exhibited a delay of cortical innervation by the thalamocortical fibers. Moreover, it has been suggested that the maturation of cortical neurons plays an important function in the incursion of thalamocortical axons in the developing cortex. Basal forebrain cholinergic neurons migrate from pallium to subpallium and represent the main cholinergic input to the cerebral cortex. Interestingly, this projection plays a crucial role in modulating cortical activity and facilitating processes of attention, learning, and memory; and has not been studied in *Lis1/sLis* mice. We hypothesized that disorganized cortex and hippocampus could affect cholinergic projections from the basal forebrain and septum, respectively, in *Lis1/sLis1* mouse. Here we first studied the basal forebrain in *Lis1/sLis1* mice during development and observed significant structural and hodological differences between wild-type and *Lis1/sLis1* embryos. In addition, septo-hippocampal projections showed a delayed development in mutant embryos. This retard may be related with the cell disorganization of the dentate gyrus in the same way that cortical plate neurons are related with the invasion of thalamocortical axons. Basal forebrain abnormalities

could contribute to explain the enhanced brain excitability and deficits in hippocampal-dependent learning behaviors in *Lis1/sLis1* mutant mice and comorbidity of cognitive symptoms associated to mental diseases.

Title: RNA Binding Protein Sfpq is required for the expression of neuron-specific long pre-mRNAs essential for brain development

Authors: *A. TAKEUCHI[1], K. IIDA[1], K. NINOMIY[1], M. ITO[2], K. OHNO[2], M. HAGIWARA[1];
[1]Dept. of Anat. and Developmental Biol., Kyoto Univ. Grad. Sch. of Med., Sakyo-Ku, Kyoto, Japan; [2]Dept. of Neurogenetics, Ctr. for Neurolog. Dis. and Cancer, Nagoya Univ. Grad. Sch. of Med., Nagoya, Aichi, Japan

Abstract: Recent methodological advances using microarray, deep-sequencing and biochemical analysis combining bioinformatics provide growing evidence for the essential roles of mRNA processing on the neural development. The mRNA processing is mediated by the RNA-binding proteins which regulate the expression of many genes co-transcriptionally or post-transcriptionally through direct interaction with pre-mRNAs. Here we found that RNA-binding protein, Sfpq (splicing factor, proline/glutaminerich) plays an essential function in mammalian

brain. In embryonic mouse brains, Sfpq is specifically expressed in nascent cortical plate neurons after they differentiate and migrate from neuronal progenitor cells, suggesting its crucial functions for the development of cerebrocortical neurons. To address the in vivo function of Sfpq, we disrupted the Sfpq gene in mice brain. Neuronal tissue specific knockout of Sfpq caused apoptosis in neurons and massive loss of brain tissues in the developing brains including neocortex, indicating that Sfpq is essential for differentiation or maturation of neurons. Next, we produced a specific antibody against Sfpq, and conducted the iCLIP analysis to identify the target of Sfpq in the mouse embryonic neocortex. Distribution of the iCLIP tags showed saw-tooth patterns on entire pre-mRNAs of more than 7400 genes with low sequence specificity. The density of the tags was highest in 5' end of introns, and gradually declined to 3' end. In these large populations of Sfpq-binding genes, only specific gene subsets which express long pre-mRNAs were significantly down-regulated in the Sfpq-disrupted mice brain. According to the Gene Ontology, these genes have essential functions for the brain development, such as cell-adhesion, cell motion, axon guidance, ion channel activity or receptor related molecules, and synaptic vesicle transport and related molecules. Our comprehensive transcriptome analysis showed that 17.4% of specifically expressed pre-mRNAs exceed 262k in differentiated neurons. These data indicate that the RNA binding protein Sfpq is required for the expression of long pre-mRNAs which play essential roles for the survival of neurons, especially in the cortical plate at the developmental stages of brain.

Institute, Dept. of Neurosci. and Pharmacology, UMC Utrecht, Utrecht, Netherlands; [3]Mol. Cancer Research, UMC Utrecht, Utrecht, Netherlands

Abstract: Mesodiencephalic dopaminergic (mdDA) neurons control locomotion and emotion and are affected in multiple psychiatric and neurodegenerative diseases, including Parkinson's Disease (PD). Homeodomain transcription factor Pitx3 is pivotal in mdDA neuron development and loss of Pitx3 results in programming deficits in a rostrolateral subpopulation of mdDA neurons destined to form the Substantia Nigra (SNc), reminiscent of the specific cell loss observed in PD. We show here that in adult knock-out mice for a second homeoprotein, Engrailed-1 (En1), dramatic loss of mdDA neurons and striatal innervation defects were observed, partially reminiscent of defects observed in Pitx3(-/-) mice. We then continue to reveal developmental crosstalk between En1 and Pitx3 through genome-wide expression analysis. During development both En1 and Pitx3 are required to induce expression of mdDA genes in the rostrolateral subset destined to form the SNc. In contrast, Pitx3 and En1 reciprocally regulate a separate gene cluster, including Cck, demarcating a caudal mdDA subset in wild-type embryos. Whereas En1 is crucial to induce this caudal phenotype, Pitx3 antagonizes it rostrolaterally. The combinatorial action of En1 and Pitx3 is potentially realized through at least three levels of molecular interaction: 1) influencing each others' expression level 2) release of HDAC-mediated repression of Nurr1 target genes and 3) modulating En1-activity through Pitx3 driven activation of En1 modulatory proteins. These findings show how two critical mediators of mdDA neuronal development, En1 and Pitx3, interplay in dopaminergic subset-specification, underlying specific molecular features, exemplified by specific vulnerability of the SNc as found in PD.

Title: Role of notch pathway in development and survival in chronic hypoxia

Authors: *P. AZAD[1], J. BROPHY[2], G. HADDAD[3];
[1]Univ. of California San Diego, La Jolla, CA; [3]Pediatrics and Neurosci., [2]Univ. of California San diego, La Jolla, CA

Abstract:
Oxygen is essential for the development and growth of all organisms. Our research is focused on understanding the molecular mechanisms that lead to injury or adaptation to hypoxic stress using *Drosophila* as a model system. To identify the genes involved in hypoxia tolerance, we screened P-element insertion lines generated by Gene Disruption Project. For hypoxia tolerance, we screened for a) eclosion rates after following the development of embryos placed in 5% O_2 to eclosion and adulthood, b) number of adult flies surviving after eclosion .Out of 2187 lines screened,44 P-element lines had eclosion rates significantly higher (>70% eclosion) than the controls (eclosion rate ~7-8%) under hypoxia. The molecular function of these lines ranged from cell cycle regulation, DNA or protein binding, ATPase activity, and transcriptionalco-regulators. In this screen, we found certain interesting candidate genes such as *sec8, cyclin E, osa, l(3)mbn, lqf* which show tremendous hypoxia tolerance during all stages of development. By bioinformatic analysis, we found that 20 out of the 44 candidate genes are linked to Notch signaling pathway, strongly suggesting that this pathway is essential for hypoxia tolerance in flies. Furthermore, we employed the UAS-Gal4 system to further dissect the role of these genes ubiquitously or in specific tissues in vivo. We found that the specific knock-down of osa in the nervous system (elav-gal4) and mushroom body (MB) significantly decreased eclosion rates. This suggests that *osa* has a specific rolein the central nervous system and under hypoxia its loss of function decreases eclosion rates. We also observed that up-regulation of *lqf* in glial cells leads to a significantly higher eclosion (93%,$P<0.001$). Our real-time PCR analysis shows that several Notch pathway genes such as *Delta* and *Enhancer of Split α* are significantly altered in the P-element lines of *lqf* and *osa* genes reinforcing our hypothesis that Notch activation plays a critical role in development under hypoxic conditions. Furthermore, by using a series of genetic crosses (using UAS and RNAi lines) we are studying the effects of activation or inhibition of Notch pathway genes on hypoxia tolerance in *lqf* gene double mutants ubiquitously and in specific tissues to prove the functional link. In flies, Notch influences the fate of cells in both the central nervous system (CNS) and peripheral nervous system (PNS). Interestingly, we found that regulation of single genes such *lqf* gene (Notch regulator via Delta ligand) in glial cells and *osa* gene in nervous system can play an important role in development during hypoxia.

Title: DNA methylation profiling of human cortical GABAergic neurons revealed by a novel flow cytometry-based nuclei separation approach

Authors: *A. KOZLENKOV[1,2], S. RUDCHENKO[3], M. WEGNER[4], M. BARBU[3], M. BIBIKOVA[5], Y. HURD[1], S. DRACHEVA[1,2];
[1]Dept. of Psychiatry, Mount Sinai Sch. of Med., New York, NY; [2]Psychiatry Res., James J. Peters VA Med. Ctr., Bronx, NY; [3]Hosp. for Special Surgery, New York, NY; [4]Lehrstuhl für Biochemie und Pathobiochemie, Inst. für Biochemie, Erlangen, Germany; [5]Illumina, Inc., San Diego, CA

Abstract: To date, the majority of the epigenetic studies of the human brain have used bulk tissue specimens, and, therefore, did not allow discerning specific contributions of various cellular populations. However, recently it has become apparent that there are significant differences in epigenetic profiles among different cell populations present in the adult brain, which warrants their in-depth epigenetic characterization. This task is especially important for the study of cortical GABAergic neurons. Whereas this group of neurons has been consistently implicated in many neurological disease conditions, the relatively small proportion of this population (~20% of all neurons in human cortex) implies that its contribution to the epigenetic profiles obtained from the bulk brain tissue can be easily masked by the contributions of other cell types in the brain.
Based on the existing nuclei sorting protocol that employs anti-NeuN antibodies to separate neuronal and glial nuclei from the postmortem human brain, we developed a novel multicolor FACS-based approach to isolate nuclei of a subpopulation of human cortical GABAergic neurons. The collected fraction was strongly enriched in neurons which developmentally derive from the medial ganglionic eminence (MGE) and include parvalbumin (PVALB)- and somatostatin (SST)-positive GABAergic neurons. In agreement with the previously published data, the isolated subpopulation comprised ~15% of all neurons. To validate the specificity of the method, we isolated RNA from sorted nuclei and confirmed by qPCR that the isolated subpopulation showed a strong enrichment of GABAergic-specific transcripts, such as *GAD1*, *PVALB*, *SST* and *LHX6*, and depletion of markers of glutamatergic neurons. We next obtained the genome-wide DNA methylation profile of the MGE-derived human cortical interneurons and compared it with that of the remaining neuronal fraction, which predominantly consisted of glutamatergic projection neurons. Thousands of CpG sites were found to be differentially

methylated between the two neuronal subpopulations, often displaying gene-specific localization. Differentially methylated sites were depleted from CpG islands and promoters. In contrast, cell type-specific differential methylation was overrepresented within distal regulatory elements. The current study opens previously unavailable opportunities to study epigenetic properties of GABAergic neurons in autopsy brains from individuals with various psychiatric conditions.

Title: Neuronal insulin regulated nestin expression when compared to IGF-1 in neuron cell cultures obtained from stem cells of fetal rat brain

Authors: *R. SCHECHTER, K. E. MILLER;
Anat. & Cell Biol., Oklahoma State Univ. CHS, TULSA, OK

Abstract: Insulin and insulin like-growth factor 1 **(IGF1**) "de novo" production by neurons has been proven by us and other laboratories. Neuronal insulin [**I(n**)] induces axonal growth and differentiation, decreases nestin positive neurons and promotes neurofilament expression. **IGF1** does not promote axonal growth, decreases neuronal differentiation, but induces neuronal survival. We quantitated the role of **I(n)** and **IGF1** on nestin expression in the axons using stem cells from fetal rat brain neuron cell cultures (**NCC**). NCC were isolated from 16 days gestational age fetal rat brain with a mouse monoclonal p-75 antibody, followed by 280 µm magnetic beads conjugated to goat anti-mouse antibody. NCC were cultured in serum free-insulin free DMEM /F12 medium (IFM), insulin media (IM) (5 ng/ml), IGF1 medium (100 ng/ml) or 5 µl/ml of a guinea pig anti-insulin antibody. Nestin was identified at 1 and 3 days of culture employing a mouse monoclonal anti-nestin antibody, followed by a goat anti-mouse antibody conjugated with FITC. Nestin was seen in neuron bodies and along axons at day 1 and day 3 of incubation. Quantitation of nestin within the IFM showed a significant decreased ($p<0.05$) at day 3 of incubation when compared to day 1. Nestin was significantly decreased ($p<0.05$) at day 1 of incubation with IM when compared to day 1 of IFM. Neurons incubated

with anti-insulin antibody for 3 days showed no significant differences in nestin concentration compared to IFM day 1, but a significant increase ($p<0.05$) was found compared to IFM day 3 and IM. Nestin quantitation showed a significant increase ($p<0.05$) within the IGF1 medium at day 1 and 3 of incubation when compared to IFM day 3 and IM. No significant difference ($p>0.05$) was found between IGF1 media, IFM day 1 and anti-insulin antibody treatment. Thus, **I(n)** promotes neuron differentiation by negatively regulating nestin. IGF1 may have a role of promoting neuronal survival, but not differentiation. Lack of insulin may induce alterations in neurons in the balance of the neuronal filaments. This is important in Alzheimer's disease associated with Diabetes Mellitus, Type I Diabetes Mellitus and Alzheimer's disease in which alterations of cytoskeleton are seen. This study and the in vivo results are in favor of insulin being produce by neurons. **I(n)** role within the brain based in the current and previous results is to regulate neuronal cytoskeleton expression. The concentration of insulin needs to be constant within the brain for this function. A "de novo" synthesis of insulin by neurons provides a constant source of insulin. This may be evident by the short half life of insulin and that pancreatic insulin secretion is induced in an episodic fashion by glucose.

Title: Retinal pigment epithelium is a Notch signaling niche in mouse retina

Authors: T.-J. HA[1], S. KIM[1], J. HATAKEYAMA[2], K. SHIMAMURA[2], Y.-Y. KONG[3], *J. KIM[1];

Abstract: To maintain vertebrate neural progenitor cell (NPC) fate, Notch is activated in NPC by its ligands expressed in adjacent cells, of which identities are largely unknown yet. To elucidate the sources of functionally active Notch ligands in mammalian retina, we negatively modulated Notch ligand activities by specific elimination of Mindbomb1 (Mib1), an ubiquitin ligase activating Notch ligands, in retinal progenitor cells (RPCs), post-mitotic retinal neurons (PMNs), or retinal pigment epithelium (RPE). The Mib1-deficient RPCs failed to induce Notch activation in neighboring RPCs, which prematurely differentiate into retinal neurons. The Mib1 in RPE was also crucial for Notch activation in RPC, whereas the Mib1 in PMNs was dispensable. We found RPE expresses Notch ligands at apical membrane that adheres to Notch1-enriched RPC apical membrane. Elimination of Notch1 and Notch2 in RPE resulted in insignificant changes, while hyperactivation of Notch signaling in RPE facilitated ciliary epithelial fate, suggesting that Notch signaling in RPE should be suppressed for supporting retinal development in non-cell autonomous manners. Together, we propose a model that a RPC acquires its fate by receiving extra Notch signals from RPE, in addition to a reciprocal Notch signaling between post-mitotic RPC daughter cells.

Title: Gene coexpression analysis identifies a molecular signature of migrating GABAergic neurons in developing human neocortex

Authors: *C. S. RAJU[1], A. STANCO[2], J. L. R. RUBENSTEIN[2], M. C. OLDHAM[1];
[1]The Eli and Edythe Broad Ctr. of Regeneration Med. and Stem Cell Res., Univ. of California, San Francisco, San Francisco, CA; [2]Dept. of Psychiatry, Univ. of California San Francisco, San Francisco, CA

Abstract: The neocortex is an extraordinarily complex, heterogeneous structure, comprised of many different cell types. During neocortical development, radial glia generate excitatory neurons that migrate radially to form the six cortical layers, followed by glial cells. In contrast, GABAergic neurons are largely derived from the ganglionic eminence in the ventral

telencephalon, and arrive in the neocortex via long-distance tangential migration. GABAergic dysfunction has been implicated in a variety of neurological disorders; it is therefore critical to understand the molecular basis for the proper specification and migration of GABAergic neurons. We have developed an unbiased method called Gene Coexpression Analysis of Serial Sections (GCASS) that can identify molecular signatures of distinct cell types in a single tissue sample. Using this method, we analyzed gene coexpression relationships in the developing neocortex of an 18 gestational week human individual and identified a molecular signature of migrating GABAergic neurons. We validated the specificity and reproducibility of this signature through immunostaining and gene coexpression analysis of several independent transcriptomic datasets generated from fetal human neocortical samples, demonstrating that it is robust across a variety of sampling strategies and technology platforms. Furthermore, we compared this signature with microarray data generated from GABAergic neurons obtained via FACS of neocortical samples from P0 CXCR7-GFP+ mice, identifying conserved and distinct patterns of gene expression between the species. Our results implicate a large number of novel genes as candidates involved in the differentiation and migration of GABAergic neurons, and offer a strategy for exploring aspects of interneuron development that may distinguish humans from other species.

Title: *In vitro* neurotrophic properties of suberoylanilide hydroxamic acid (SAHA), a pan histone deacetylase inhibitor

Authors: *S. SHUKLA[1], B. L. TEKWANI[2], L. A. WALKER[2];
[1]Dept. of Pharmacology, Univ. of Mississippi, Sch. of Pharm., University, MS; [2]Dept. of Pharmacology, Univ. of Mississippi, NCNPR, Sch. of Pharm., University, MS

Abstract: Degeneration of neurons is the major cause of the neurodegenerative diseases. Neurodegenerative diseases including Parkinson's disease (PD), Alzheimer's disease (AD), Huntington's disease (HD) and Amyotrophic Lateral Sclerosis (ALS) occur as a result of progressive loss of structure or function of neurons, including death of neurons. Neurotrophic actions and neuroprotection leading to neuroplasticity and neurite outgrowth are important markers for neuroregeneration. Neuritogenesis or neuritic outgrowth is a fundamental process in the differentiation of neurons and plays an important role in neuronal development and formation of synapses. These processes are regulated by extrinsic and intrinsic determinants that affect gene expression profiles and signal transduction pathways. Within the past decade, there have been many studies showing neuroprotective effects of inhibitors of histone deacetylases (HDAC). Evaluation of a battery of HDAC inhibitors showed promising neurotrophic effects of SAHA, a pan HDAC inhibitor that binds to the catalytic site of the enzyme, inhibits class I and class II HDACs, arrests cell growth in a wide variety of transformed cells in culture and the first HDAC inhibitor approved by FDA for treatment of chronic T-cell leukemia. The neurotrophic properties of SAHA were investigated in detail employing NeuroScreen1 (NS-1) cell line, derived from PC12 (rat adrenal pheochromocytoma) cells. NS-1 cells were treated with SAHA for 72 hrs. Cytotoxicity was measured and neurite outgrowth was monitored as neurite numbers and lengths by digital microscope imaging and NIS element software. SAHA independently produced significant increase in neuritic outgrowth. Further, to investigate the mechanism for SAHA-induced differentiation of NS-1 cells the MEK1/2 inhibitors (PD98059 and U0126) and PI3K inhibitor (LY294002) were tested. The neurotrophic actions of both NGF and SAHA were almost completely abolished by co-treatment of the NS-1 cells with the inhibitors of MEK1/2 & PI3K. SAHA produced selective time-dependent hyperacetylation of histones as well as non-histone proteins in NS-1 cells as probed by anti-acetylated lysine antibody. Treatment of NS1 cells with SAHA induced phosphorylation of ERK1/2 at 4 hrs confirming role of ERK pathway in differentiation. In conclusion, SAHA exerts neurotropic action via activation of MEK1/2 & PI3K pathways. Bioactive small molecules with neurotrophic and neuritogenic actions, like SAHA identified in the present study, hold great promise as therapeutic agents for treatment of neurodegenerative diseases and neuronal injuries by virtue of their ability to stimulate neuritic outgrowth.

Title: An alternative splicing factor Celf4 is required for early retinal neuronal differentiation

Authors: A. R. BANDAY, *R. KANADIA, S. CONGDON;
Univ. of Connecticut, Storrs, CT

Abstract: RNA-binding proteins are reported to be involved in several complex neurological diseases. Recently a RNA-binding protein Celf4, which is both an alternative splicing factor and a RNA-transporter, has been implicated in epilepsy disorder in human and mice. In the mouse brain Celf4 is expressed in excitatory neurons of the cerebral cortex and hippocampus. However, the role of celf4 in the development and function of the retina remains unexplored. Here, we have examined the expression pattern and possible role of Celf4 in the developing mouse retina. We analyzed the expression of Celf4 by RT-PCR across the mouse retinal development and found two alternatively spliced isoforms that are unique to the retina. To visualize the expression of Celf4 mRNA and protein in the different cell types of the developing retina we employed in situ hybridization and immunoflourescence (IF), respectfully. We found at embryonic day 12 (E12) and E14 that Celf4 was expressed in the nucleus of retinal ganglion cells. Later in the retinal development from E18 through postnatal day (P14) Celf4 expression was observed both in the nucleus and cytoplasm in ganglion (E16), amacrine (E16), bipolar (P8) and photoreceptor cells (P8). However, in the adult mouse, Celf4 expression is entirely cytoplasmic, suggesting that its role in alternative splicing might be restricted to pre-natal development. These distinct roles of Celf4 may be assigned to the two isoforms that were found in the retina. Specifically, it might be regulated via differential localization and /or post-translation modification site such as phosphorylation. Interestingly, bioinformatics analysis revealed that there was a potential phosphorylation site for PKC-alpha at Serine 164 on the larger retinal isoform (Isoform A) but not on the smaller isoform (Isoform B). Preferential phosphorylation could confer different functions to the two isoforms.
In order to investigate the function of Celf4 in the mouse developing retina, we used constitutively knocked out (KO) mice. Our preliminary analysis showed that in the KO retina at E16, there was a failure to close the retinal fissure, which results in retinal coloboma observed at birth. In all, this suggests that celf4 plays an important role in normal retinal development. In the future, we will employ a conditional KO mouse, to further understand the function of celf4 by identifying its targets in embryonic and postnatal retinal development.

Title: The RNA-binding protein motif protein 3 (RBM3) regulates the LIN28-let-7 axis and neural differentiation

Authors: A. GROMOVA[1], C. SPEVAK[2], J. PILOTTE[1], *P. VANDERKLISH[1];
[1]Dept of Cell and Mol. Biol., Scripps Resch Inst., LA JOLLA, CA; [2]Mem. Sloan-Kettering Cancer Ctr., New York, NY

Abstract: Neurogenesis is a fundamental process underlying brain development and plasticity, and it is dysregulated in a broad spectrum of psychiatric and degenerative conditions. Multiple steps in the process of neurogenesis are critically influenced by microRNAs (miRNAs) - non-coding RNAs that regulate mRNA translation - and by RNA-binding proteins (RNA-BPs) that regulate miRNA biogenesis. A pivotal role in early neurogenesis is played by LIN28, an RNA-BP that suppresses the biogenesis of let-7 miRNAs that target de-differentiation factors, thus maintaining pluripotency. The mRNA encoding LIN28 is itself targeted by let-7, thus creating a "bi-stable switch" wherein either LIN28 or let-7 dominates to favor pluripotency or differentiation, respectively. Signaling pathways that regulate this switch, and the biogenesis of other miRNAs controlling neurogenesis, are thus of fundamental importance in neural development and plasticity. In prior work, we found that the RNA-binding motif protein 3 (RBM3) - an RNA-BP induced by cell stress - is highly expressed in stem/progenitor cells and strongly promotes the biogenesis of all let-7 family members, as well as other miRNAs target LIN28. Based on these findings, we hypothesized that RBM3 modulates the state of the LIN28-let-7 axis to promote neural differentiation. Using the P19 embryonic carcinoma cell line and both mouse and human embryonic stem cells, we found that induction of RBM3 expression promoted let-7 biogenesis and, accordingly, reduced LIN28 expression. Conversely, siRNA-mediated knockdown of RBM3 resulted in reduced let-7 biogenesis and increased LIN28 expression. In the retinoic acid (RA) model of P19 neural differentiation, RBM3 was specifically upregulated during the neurosphere stage, correlating with increased let-7 biogenesis. Knockdown of RBM3 attenuated RA-induced neural differentiation, whereas overexpression of RBM3 promoted it, even in the absence of a neurosphere step and RA. Subsequent studies revealed that the effects of RBM3 on the LIN28-let-7 axis are negatively regulated by post-translational modifications of RBM3 mediated by kinase and protease pathways that contribute to pluripotency. Preliminary analyses of a *Rbm3* KO mouse revealed lower cell counts in hippocampus, and evidence of reduced neurogenesis. Overall, our data suggest that RBM3 is an

important regulator of neurogenesis through its effects on miRNAs, with the apparent capacity to override the influence of LIN28 during early stages of cell commitment. The fact that RBM3 is induced by a wide range of cellular stresses and disease states suggests that it may mediate some of the known effects of these states on neurogenesis.

Title: VEGF-C/VEGFR3 signaling in adult hippocampal neural stem/progenitor cells and response to physical exercise

Authors: *J. HAN[1], K. BAKER[1], N. FOURNIER[2], C.-F. CALVO[4], R. DUMAN[2], A. EICHMANN[1], J.-L. THOMAS[4,3];
[1]Cardiol., [2]Psychiatry, [3]Neurol., Yale Univ., New Haven, CT; [4]Univ. Pierre et Marie Curie-Paris 6, Paris, France

Abstract: Vascular endothelial growth factor family molecules (VEGFs) and their receptors (VEGFRs) are essential for blood vessel and lymphatic vessel growth. Previous studies from our laboratory revealed that VEGF-C, a member of VEGF family, can affect the developing and adult central nervous system by promoting the activity of neural stem/progenitor cells. In the adult subventricular zone, this effect is directly mediated on neural stem/progenitor cells by VEGFR-3, the specific VEGF-C receptor (Genes Dev, 2011). It remained to be determined whether this function extended to other neural stem cell (NSC) populations of the adult brain, and what its physiologic consequences were. We have therefore investigated VEGF-C/VEGFR-3 signaling in the subgranular zone (SGZ) of the dentate gyrus (DG) in the hippocampal formation, which is one of the specialized regions in which new neurons are generated from NSCs in the adult. The hippocampus is moreover a key regulatory center of cognitive functions and mood. Using BAC-Vegfr3::YFP reporter mice, we detected a specific Vegfr3 expression in SGZ NSCs and early progenitor cells, but not in differentiated neuronal cells. Overexpression of VEGF-C by intra-hippocampal delivery of adeno-associated virus (AAV9)-VEGF-C increased cell division of SGZ VEGFR-3-stem/progenitors without a pro-angiogenic effect. Following NSC-specific deletion of Vegfr3 by tamoxifen treatment of Glast-CreERT2, Vegfr3 flox/flox mice SGZ neurogenesis was not affected in basal conditions. However, neurogenesis was impaired in

response to voluntary exercise activity, which is known to activate quiescent NSCs. Exercise activity was associated with increased levels of VEGFR-3 ligand (VEGF-C/D) expression in the DG. We are currently exploring whether VEGF-C/VEGFR-3 might regulate the positive effect of physical exercise on mood, which has already been suggested to be SGZ-neurogenesis-dependent. Preliminary studies in the rat indicate that mood state is impaired following local delivery of AAV9-VEGF-R3-Ig, which decreases the availability of hippocampal VEGF-C and D.
These results confirm VEGF-C/VEGFR-3 signaling as a hallmark of neural stem/progenitor cells in the adult brain. Our data also suggest that this signaling pathway contributes to mediate the specific response and activity of SGZ neural stem/progenitors to physical exercise, with possible consequences on mood.

Title: Functional roles and regulation of PTPs during neuronal differentiation

Authors: *B.-S. HAN, S.-Y. KIM, W.-K. KIM, K.-H. BAE, S.-C. LEE;
Res. Ctr. for Integrative Cellulomics, Korea Res. Institue of Biosci. and Biotech., Daejeon, Korea, Republic of

Abstract: The phosphorylation status of tyrosine residues on proteins is fundamentally important for the control of different functions of the cells and is the results of the balance between protein tyrosine kinases (PTK) and protein tyrosine phosphatases (PTP). Improper control of tyrosine phosphorylation levels has been linked to a variety of diseases. Several reports have provided evidences that PTPs play an important role in neuronal morphogenesis, neuronal development, axonal guidance, and synaptogenesis. Although important advances have been made in this field, it still needs to be addressed in more detail about the signaling mechanisms involved in this processes. In this study, we performed to investigate PTPs gene expression profiling from mouse embryonic stem cells (J1 ES) to J1 ES derived neurons. Neurons generated from undifferentiated J1 ES cells showed neuronal morphology such as neurite outgrowth, and expressed neuronal markers such as microtubule-associated protein 2, β-

tubulin type III. During neuronal differentiation, several PTPs showed differentially expressed patterns between ES cells and ES derived neurons. Functional studies of PTPs provide a valuable clue for the understanding of neurogenesis mechanism.

Abstract: The behavioral and cognitive functions of frontal cortex require the interaction of diverse neurons and glial cells with specific roles arising from their location, connections with other brain cells, as well as each cell's intrinsic, epigenetically defined molecular identity. Dynamic epigenetic changes, including variant histones, histone modifications and DNA methylation, are implicated in brain development, maturation and learning. Among these, DNA methylation is a stable covalent modification that can persist in post-mitotic cells throughout the lifetime and thus confers a capacity for long-term memory of cellular identity. At the same time, the DNA methylation status at each of ~1 billion sites across the genome is potentially an information-rich and flexible epigenetic modification that can be altered by cellular activity and which is implicated in learning and memory. Yet elucidating the role of DNA methylation in brain function has been hampered by the lack of precise knowledge of the genomic distribution of this mark in brain cell types. We will present the genome-wide composition, patterning, cell-specificity and dynamics of DNA methylation at single-base resolution in frontal cortex of humans and mice throughout their lifespan. Extensive methylome reconfiguration occurs during development from fetal to young adult. In this period, coincident with synaptogenesis, highly-conserved non-CG methylation accumulates in neurons, but not glia, to become the dominant form of methylation in the genome. We uncovered surprisingly complex features of brain cell DNA methylation at multiple scales, first by identifying intragenic methylation patterns in neurons and glia that distinguish genes with cell-type specific activity. Second, we find >100,000 developmentally dynamic and cell-type specific differentially CG-methylated regions that are enriched at putative regulatory regions of the genome. Third, we report a novel mCH signature that identifies genes escaping X-chromosome inactivation in neurons. Finally, whole-genome detection of 5-hydroxymethylcytosine (hmC) at single-base resolution revealed that this mark is present in fetal brain cells at locations that lose CG methylation and become activated during development. CG-demethylation at these hmC-poised loci depends on Tet2 and Tet3 activity. Overall, brain cell DNA methylation has unique features that are precisely conserved, yet dynamic and cell-type specific.

Title: The role of CIP4 in neuroblastoma cell proliferation and differentiation

Authors: P. SUTHIVANICH[1], S. KONGOUN[1], J. KWANTONGDEE[1], K. TAYLOR[2], E. W. DENT[3], *W. SAENGSAWANG[4,1];
[1]Physiol., Fac. of Science, Mahidol Univ., Bangkok, Thailand; [2]Neurosci. Training Program, [3]Neurosci., Univ. of Wisconsin-Madison, Madison, WI; [4]Neurosci., Mahidol Univ., Bangkok, Thailand

Abstract: CIP4, a member of the F-BAR family of proteins, plays important roles in various cellular events including endocytosis and membrane protrusion in several cell types. In primary cortical neurons CIP4 has been shown to induce actin-dependent veil protrusion between filopodia, which results in inhibition of neurite formation. However, the roles of CIP4 in cell proliferation and neuronal differentiation are not known. In this study we found that CIP4 is highly expressed during a very early stage of mouse brain development (E10.5); a time at which neuronal precursors are actively proliferating. To begin to determine whether CIP4 plays a role during neuronal proliferation and differentiation we used two types of cells whose differentiation can be tightly regulated, mouse cathecholaminergic neuroblastoma (CAD) and dopaminergic neuroblastoma (SH-SY-5Y) cells. We show that CIP4 is highly expressed in both cell types when the cells are actively proliferating but decreases significantly during differentiation. In addition, overexpression of CIP4 resulted in a decrease in neuroblastoma cell differentiation. These results suggest that CIP4 may be playing an important role during an early stage of brain development, possibly by inhibiting neuronal differentiation. Further experiments will determine the underlying mechanisms by which CIP4 appears to inhibit neuronal differentiation.

Title: Dopaminergic transcriptional determinants repress non-dopaminergic transcription

Authors: *N. KEE, J. MONG, T. PERLMANN;
LICR, Karolinska Inst., Stockholm, Sweden

Abstract: A cell's path through development from a pluripotent embryonic stem cell to a specific, differentiated adult cell at a precise location in the body, and with a precise function, involves the complicated task of modelling the genome such that desired transcriptional programs emerge, while undesired programs do not. This task is orchestrated, at least in part, through the temporal action of countless patterning and signalling molecules, temporal cellular clocks, as well as stochastic events, and which is ultimately realised at the genomic level by the coordinated action of transcription factors that direct the transcription of these desired programs, while undesired programs are not transcribed. This poses a challenge particularly in the central nervous system, where hundreds of distinct neuronal populations, each serving a particular role, need to be generated. Moreover, the molecular differences between some of these populations, while imperative to their functions, may be quite subtle. We have investigated the influence of dopaminergic transcription factors on the transcriptome of non-dopaminergic neural subpopulations, where they appear to serve a function to repress transcription of non-dopaminergic genes. This role is most strongly seen for Pitx3, a post-mitotic transcriptional determinant found exclusively in ventral midbrain dopaminergic neurons. The observation that a post-mitotic, dopaminergic specific transcription factor is involved in repression of genes not normally expressed in dopamine neurons invites the theory that even after exiting the cell cycle, the dopaminergic identity is not yet concretely specified, and that at this moment transcriptional determinants continue to both promote the dopaminergic program, and repress undesired programs.

Abstract: Adult neurogenesis in the adult brain has been shown to exist primarily in the dentate gyrus (DG) of the hippocampus and the subventricular zone (SVZ) of the lateral ventricles. These two distinct pools of neural stem/progenitor cells (NSCs) generate different subtype neurons and respond independently to environmental cues. However, the mechanisms that differentially control neurogenesis in these two brain regions are still unclear. The RNA binding protein Elavl4 (HuD) is a regulator of neuronal differentiation and involved in paraneoplastic encephalomyelitis disorders with learning deficits. Here, we found HuD has distinct expression patterns in these two neurogenic regions. HuD is expressed throughout the process of SVZ neurogenesis from NSCs to maturation neuron, whereas HuD only expressed in NSCs and doublecortin-positive immature neuron in the DG. We found that HuD exhibit differential regulatory roles in in NSCs derived from these two neurogenic regions. Furthermore, we found HuD may regulate SVZ-NSCs and DG-NSCs differentiation through different molecular mechanisms. Taking together, investigation of differential regulation of SVZ and DG NSCs by HuD not only shed light on a mechanism that governs the different neurogenesis in these two neurogenic zones, but also provide mechanistic insights into paraneoplastic encephalomyelitis.

Abstract: Duchenne muscular dystrophy (DMD) is a severe X-linked myodegenerative disease caused by defective expression of full length dystrophin (Dp427) consequent to mutations in the DMD gene. Besides muscle degeneration, DMD patients also experience forms of cognitive impairment, neurological and autonomic disorders, altered scotopic electroretinogram and red-green color vision defect. In normal retina, different dystrophin isoforms, including Dp427, are present at the ribbon synapses between photoreceptors and bipolar cells, in the inner and outer nuclear layers and in amacrine cells. However, despite several studies, little is still known on how lack of Dp427 and its isoforms induce the described retinal physiological alterations. In this study, we evaluate differences in both morphological differentiation of the retinal layers and gene expression during post-natal development of wild type (WT) and dystrophic *mdx* mouse retina. Discrimination of the different retinal layers, a phenomenon occurring after birth, was analyzed on paraffin-embedded eye sections, from P5, P10 and 6-7 week old mice. The thickness of different layers, i.e. outer segment of photoreceptors (OSP), outer nuclear and plexiform layers, inner nuclear and plexiform layers and ganglion cell layer (GCL), was measured from 3-4 animals/genoptype and statistically compared. A significant reduction in the thickness of both the OSP (where visual pigments are located) and GCL was observed at P5, when retinal cells are still migrating in their final position. Moreover, at this same date, segregation of the different cells in the appropriate layer of the WT mouse retina starts to become evident, while is still confused in the *mdx* genotype, suggesting an early asynchronous migration of retinal cells to their final position. All these gross dissimilarities disappear in older mice. Differences in mRNA expression between the two genotypes were, then, evaluated by RNA Sequencing on P5 mice. Combining edgeR and DESeq methods of analysis, about 50 genes were significantly up or down regulated (by at least one fold) in *mdx* mice compared to WT. The majority of the down regulated genes was related to cell development, transcription, cytoskeleton dynamics and cell stress response. In conclusion, our data suggest that, as in other nervous system regions, also in the retina dystrophin isoforms play a major role in neural development and early differentiation.

Abstract: The cell-autonomous regulators or extrinsic signals sufficient to specify retinal ganglion cell (RGC) fate in the developing retina or from adult stem cells remain largely obscure. Here we report a new molecular pathway involving Sox4/Sox11 in parallel to GDF-11/Math5 signaling that is required for RGC differentiation from retinal progenitor cells (RPCs) and optic nerve formation in vivo, and sufficient to potentiate the differentiation of both mouse and electrophysiologically active human RGCs from induced pluripotent stem (iPS) cells. We further describe a regulatory network whereby the previously described inhibitor of RGC differentiation, REST, depends on suppression of Sox4 expression, and provide evidence for a novel soluble regulator of RGC differentiation, the TGFß family member GDF-15, which requires Sox4 to induce RGC differentiation. Although our data suggests that Sox4 and Sox11 are independently required for RGC development, the two family members interact such that the normal SUMOylation of Sox11, which decreases its nuclear localization and suppresses its pro-RGC activity, is decreased in the absence of Sox4, allowing Sox11 to compensate for Sox4

absence. These data define a novel molecular network necessary and sufficient for RGC fate specification and suggest a number of novel pro-RGC molecular manipulations which may provide potential promise for cell replacement-based therapies for glaucoma and other optic neuropathies.

Title: Crosslinking-induced endocytosis of acetylcholine receptors by quantum dots

Authors: C. LEE[1,2], H. L. ZHANG[1], L. GENG[1], *H.-M. B. PENG[1];
[1]Div. of Life Sci., The Hong Kong Univ. of Sci. and Technol., Kowloon, Hong Kong; [2]Dept. of Physiol., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: In majority of patients with myasthenia gravis (MG), anti-acetylcholine receptor (AChR) antibodies are generated in their immune system, which target the postsynaptic AChR clusters and thus compromises membrane integrity of neuromuscular junctions (NMJs) leading to muscle weakness. The antibody-induced endocytosis of AChRs in the postsynaptic membrane represents the initial step in MG pathogenesis; however the molecular mechanisms underlying AChR endocytosis remain largely unknown. Here, we used multivalent quantum dots (QDs) to mimic the pathogenic antibodies for inducing the crosslinking and internalization of AChR from the postsynaptic membrane. By labeling the muscle cells with biotin-conjugated α-bungarotoxin followed by QD-conjugated streptavidin, we were able to differentiate the surface versus internalized AChRs by comparing their size, fluorescence intensity, trajectory, and subcellular localization of the QD signals. These crosslinking-induced internalized AChRs were highly co-localized with an early endosomal marker. QD-induced AChR endocytosis was mediated via clathrin-dependent, and caveolin-independent, mechanisms. Nocodazole or cold temperature treatment, that largely disrupted microtubule structures, arrested the movement of QD-induced

AChR vesicles inside the cells. Furthermore, activation of agrin/MuSK signaling pathway, by either agrin treatment or overexpression of MuSK and rapsyn, significantly suppressed QD-induced internalization of AChRs, suggesting synaptogenic signals increase the stability of surface AChRs. Lastly, QD-induced AChR crosslinking potentiated the dispersal of prepatterned AChR clusters upon synaptic induction. Taken together, this study reports a novel approach to study the trafficking mechanisms of AChRs upon receptor crosslinking and endocytosis, and demonstrates the protective action of agrin-MuSK signaling in the crosslinking-induced AChR endocytosis.

Abstract: Synaptogenesis is regulated by a well-defined sequence of events that occur during development. Although pre-synaptic axons were initially considered the leading players in synapse formation, recent studies in the neuromuscular junction (NMJ) demonstrate that post-synaptic development precedes and influences axonal guidance. The functional significance of this temporal sequence remains unknown. In the present study, we leveraged the genetic malleability of zebrafish to artificially reverse the temporal expression of pre- and postsynaptic components. By exploiting the rapid external development and transparency inherent to zebrafish, we could explore the in vivo manifestations of this perturbation.
We generated a transgenic zebrafish line in which the chemical RU486 controlled temporal expression of acetylcholine receptors (AChRs). This inducible system was crossed into a paralyzed mutant zebrafish line lacking postsynaptic AChRs in the NMJ. When AChRs were expressed before the arrival of neuronal axons, synapse formation proceeded normally leading to

the functional rescue of paralyzed larvae and their survival to adulthood. Conversely, larvae in which the timing of axon arrival and receptor expression was reversed displayed compromised locomotion and synapse transmission. Under this condition, AChR localization occurred independent of the presence of neuronal axon terminals. Although nerve terminals were differentiated prior to AChR expression, motor neurons followed postsynaptic cues to guide axons toward newly expressed AChRs. Unexpectedly, electrophysiological recordings revealed a complete lack of miniature end plate currents, despite the presence of evoked postsynaptic currents.
These data provide the first evidence that sequential expression of pre- and postsynaptic components plays a critical role in the function of the developing synapse. In particular, reversing the temporal expression of pre- and postsynaptic components leads to inhibition of spontaneous vesicle release, which to our knowledge has not been observed in any other synapse.

Title: RPM-1 functions through ANC-1 and beta-catenin to regulate synapse formation and axon termination

Authors: E. D. TULGREN[1], S. M. TURGEON[2], K. J. OPPERMAN[2], *B. GRILL[2];

Abstract: Mutations in Nesprin-1 and 2 (also called Syne-1 and 2) are associated with numerous diseases including: schizophrenia, autism, cerebellar ataxia, cancer and Emery-Dreifuss muscular dystrophy. Nesprin1 and 2 have conserved orthologs in flies and worms called MSP-300 and abnormal nuclear Anchorage (ANC)-1, respectively. The Nesprin protein family mediates nuclear and organelle anchorage and positioning, as well as Golgi trafficking. In the nervous system, the only known function of Nesprin-1 and 2 is in regulation of neurogenesis and neural

migration. It remains unclear if Nesprin-1 and 2 regulate other functions in neurons. Using a proteomic approach in C. elegans, we found that ANC-1 binds to the Regulator of Presynaptic Morphology (RPM)-1. RPM-1 is part of a conserved family of signaling molecules called Pam/Highwire/RPM-1 (PHR) proteins that regulate axon guidance, axon termination and synapse formation in developing neurons. Studies on invertebrates have shown that the PHR proteins regulate axon regeneration and Wallerian degeneration in mature neurons. We have found that anc-1 regulates axon termination in the mechanosensory neurons, and synapse formation in the GABAergic motor neurons of C. elegans. Our genetic analysis indicates that anc-1 functions through the beta-catenin bar-1. We have also found that the anc-1/bar-1 pathway functions cell autonomously, downstream of rpm-1 to regulate neuronal development. Dominant negative analysis indicated that ANC-1 binding to the nucleus is required for its function in axon termination and synapse formation. Our study highlights a new role for ANC-1 in neuronal development, and unveils a new mechanism by which RPM-1 functions. At present, our findings represent the first genetic link between RPM-1 and a pathway that is regulated by extracellular signals, such as Wnts.

Title: Wnt signaling in the formation of neuromuscular junction

Authors: *L. WANG, Y. ZOU;
UCSD, San Diego, CA

Abstract: Wnt signaling plays important roles in axon guidance and synapse development. However, its functions in the guidance of phrenic nerve and the formation of neuromuscular junction (NMJ) are not well understood. Here we explore the function of Wnt signaling using several genetic tools. We first analyze the overall termination patterns of the phrenic nerve and found that acetylcholine receptor (AChR) clusters show wider distribution in Frizled3 and Celr3

knockout mice, whereas no change was observed in Wnt4 mutant mice, potentially due to functional redundancy by other Wnts. This may be caused by the guidance defect of phrenic nerve or the defect in prepatterning of AChR clusters. Furthermore, we also observe that synatophysin signal is significantly reduced in the Celsr3 knockout mice. Taken together, these observations indicate an important function of Wnt signaling in regulating the proper development of neuromuscular junction.

Title: Glial cells influence synaptic plasticity of competing nerve terminals at the mammalian neuromuscular junction

Authors: *H. DARABID[1,2], R. ROBITAILLE[1,2];
[1]Physiol. - Neurosciences, Univ. De Montreal, Montreal, QC, Canada; [2]Groupe de recherche sur le systeme nerveux central, Universite de Montreal, Montreal, QC, Canada

Abstract: The precise wiring of synaptic connections is shaped by elimination of supernumerary inputs competing for the innervation of the same target cell. At the neuromuscular junction (NMJ), this competition depends on the synaptic efficacy of competing terminals which strengthens one input and weakens the others, leading to their elimination. However, little is known about the synaptic activity and plasticity of competing terminals. Moreover, the role of glial cells during synaptic competition remains ill defined despite their importance in the modulation of synaptic efficacy and plasticity at adult NMJs. Therefore, the goal of this work was to study synaptic plasticity of strong and weak terminals during synaptic competition and their interaction with perisynaptic Schwann cells (PSCs), glial cells at NMJs. We performed

intracellular recordings from dually innervated P7-8 mouse *Soleus* muscle fibres to assess synaptic activity and monitored PSC activity using confocal Ca^{2+} imaging. PSCs were loaded using single cell electroporation of the Ca^{2+} indicator Fluo-4 and the morphological dye Alexa 594. PSCs decode synaptic competition as revealed by tight relationship between the size of Ca^{2+} responses induced by the high frequency stimulation of each independent input and their synaptic strength (i.e. weak input generated smaller Ca^{2+} responses than the strong one). Interestingly, at the same NMJ, the strong input showed a long-lasting potentiation of neurotransmission while the weak one displayed only a small transient potentiation. Bath application of the $A2_A$ receptor antagonist SCH 58261 blocked the potentiation at weak and strong inputs. To determine whether the differential plasticity of competing terminals was related to PSCs Ca^{2+} responses, single PSCs were directly activated by photoactivation at 405 nm light of NP-EGTA (a caged Ca^{2+} molecule) electroporated in PSCs. A direct induction of a large Ca^{2+} response (mimicking activation by strong inputs) resulted in a long-lasting potentiation of the strong input while the weak terminal displayed only a transient one. However, an induction of a small Ca^{2+} response did not affect the synaptic activity of the competing terminals. Finally, photoactivation of Diazo-2 (photoactivable BAPTA) blocked PSCs Ca^{2+}-responses and altered synaptic plasticity.
Altogether, these data indicate that glial cells decode synaptic competition at NMJs and govern synaptic plasticity of competing nerve terminals. The differential plasticity of strong and weak inputs likely reflects changes in synaptic efficacy of competing terminals which could influence the outcome of synaptic competition and elimination.

Title: Postsynaptic activity is crucial for synapse elimination

Authors: Y. CHONG, *E. J. COOPER;
McGill Univ., Montreal, QC, Canada

Abstract: During development, as many neural circuits become established, the afferent inputs generally refine their connections through a process of synapse competition and elimination. For

synapse elimination to occur, the competing presynaptic axons must fire asynchronously. However, the role for postsynaptic activity in this process is less clear. It is frequently assumed that co-incident pre- and postsynaptic activity stabilizes synapses; yet we showed recently that silent synapses are not eliminated but can persist for months. This prompted us to ask whether postsynaptic activity is necessary for competition and synapse elimination.
To address this issue, we have extended our investigations on synaptic connections between preganglionic neurons and postganglionic sympathetic neurons in the superior cervical ganglion. We use mice with a deletion in the α3 nicotinic ACh receptor (nAChR) subunit gene because sympathetic ganglia in these α3 KO mice have no synaptic transmission and postganglionic sympathetic neurons have no EPSPs. None the less, the preganglionic axons in α3 KO mice form morphologically normal, but electrophysiologically silent synapses on sympathetic neurons; these silent synapses persist for at least 2-3 months (as long as we examined them). To determine how preganglionic axons compete for sympathetic neurons when postsynaptic activity is absent, we labeled presynaptic axons and postsynaptic neurons with lipophilic dyes, immunostained for pre- and postsynaptic markers, and used confocal microscopy to image connections.
In 1 month old WT mice, a single preganglionic axon established several contacts along the dendrites of a single sympathetic neuron. In contrast, in 1 month old α3 KO mice, we observed several preganglionic axons converging and circling the soma of individual α3 KO sympathetic neurons. These morphological results support our electrophysiological data: in WT mice, the number of preganglionic axons functionally innervating a sympathetic neuron was reduced from ~7-9 to ~2-4 over the first postnatal month. On the other hand, in α3 KO mice at 1 month, sympathetic neurons remained innervated by ~7-9 preganglionic axons. These results demonstrate that postsynaptic activity is crucial for synapse elimination because when it is absent, competition among axons does not occur and synapses are not eliminated. Our finding suggests that the refinement of synaptic connection requires an activity-dependent retrograde signal.

Title: Characterization of *Drosophila* neto isoforms and their role at the neuromuscular junction

Authors: *O. E. IGIESUOROBO[1], C. RAMOS[1], D. SANDSTROM[2], M. SERPE[1];
[1]Unit on Cell. Communication, Natl. Inst. of Health/ NICHD, Bethesda, MD; [2]Lab. of Mol. Biol., Natl. Inst. of Health/ NIMH, Bethesda, MD

Abstract: Synaptogenesis requires the recruitment of neurotransmitter receptors, which comprises of their assembly, trafficking, and stabilization at specific membrane locations. The *Drosophila* neuromuscular junction (NMJ) is a glutamergic synapse that shares common features with mammalian central synapses. The ionotropic glutamate receptors (iGluRs) present at the NMJ are heterotetrameric complexes composed of three essential subunits - GluRIIC, GluRIID, GluRIIE - and either GluRIIA or GluRIIB. The mechanism underlying the clustering and stabilization of iGluRs at the postsynaptic densities (PSDs) is a major question in the field. Our lab has identified and characterized the *Drosophila neto* (*neuropilin* and *tolloid*-like) as an essential gene required for clustering of both iGluRs types at the NMJ. *neto* null mutant embryos are completely paralyzed and die with no detectable iGluR clusters at their NMJ. Our previous studies revealed that Neto functions as an essential component of the iGluR complexes and is absolutely required for iGluR clustering, organization of PSDs, and synapse functionality. *neto* locus encodes for two isoforms, Neto-A and Neto-B, generated by alternative splicing. Neto-A and Neto-B isoforms share similar extracellular and transmembrane domains but contain different intracellular parts. These two isoforms are conserved in *Drosophilidae* and appear to be differentially expressed during development. We have confirmed that both isoforms are expressed in the larval body-wall muscles in *D. melanogaster*. Furthermore, either isoform could rescue the iGluRs clustering defects and embryonic lethality of *neto* null mutants. Using isoform specific mutants, rescue constructs, and electrophysiology we are investigating the role of these isoforms in synaptic clustering of iGluRs. Preliminary morphological analyses suggest that Neto-B specifically influences the synaptic accumulation of the type-A iGluR complexes. Furthermore, electrophysiological recordings in an allelic series of *neto-B* mutants revealed quantal sizes that correlate with GluRIIA levels. These findings indicate that the two Neto isoforms may have distinct and non-redundant functions in synapse assembly at the *Drosophila* NMJ.

Title: Systematic characterization of synaptic morphogenesis and architecture in *Drosophila* homologs of neuropsychiatric susceptibility genes

Authors: *B. KIRAGASI, D. DICKMAN;
neuroscience, USC, Los Angeles, CA

Abstract: Synapses are robust molecular machines for reliably transmuting electrical and chemical signals while maintaining stable nervous system function. As such, these complex cellular junctions require exquisite control of physical topology and subsynaptic architecture to permit efficient transmission as well as the modifications necessary for plasticity. New genetic, genomic, and biochemical approaches over the past few years have led to an unprecedented discovery of synaptic genes implicated in a wide range of poorly understood neuropsychiatric diseases with little understanding of their possible roles in sculpting synaptic morphogenesis and structure. We have established a collection of 212 RNA interference (RNAi) transgenes that target Drosophila homologs of synaptic genes recently implicated in a variety of neuropsychiatric diseases, including schizophrenia, autism, Fragile X Syndrome, and bipolar disorder. Using this collection, we have undertaken a systematic screen of synaptic structure and morphogenesis at the Drosophila neuromuscular junction, a model glutamatergic synapse. Target synaptic genes were knocked down both pre- and post-synaptically and analyzed using confocal microscopy following immunohistochemical labeling of presynaptic active zones and postsynaptic densities. We quantified synaptic size, bouton number, active zone numbers and densities, as well as postsynaptic receptor structures. These efforts have revealed novel genes required for specific aspects of the morphogenesis or molecular architecture on both sides of the synapse. Interestingly, several genes cluster into common signaling pathways and phenotypes associated with specific diseases. Data will be presented on some of the most unique alterations in synaptic structure observed as well as secondary analysis on gene localization and function. Together, this screen will establish a foundation to explore how multiple signaling and effector molecules are integrated to ensure reliable synaptic morphogenesis and how dysfunction in these processes may contribute to neuropsychiatric disease pathogenesis.

Title: Live imaging of activity-dependent synaptic refinement in *Drosophila* embryos

Authors: F. VONHOFF, *H. S. KESHISHIAN;
MCDB Dept., Yale Univ., New Haven, CT

Abstract: The pruning of off-target contacts is a crucial mechanism for establishing precise neural networks during development. Neural activity plays an important role in synaptic refinement in various systems, including the vertebrate visual system, where low frequency (<0.01 Hz) calcium and cyclic nucleotide oscillations are required for synaptic refinement. Activity-dependent synaptic refinement also occurs at the *Drosophila* neuromuscular junction (NMJ), where oscillatory neural activity and presynaptic calcium signaling, acting via CaMKII, modulate the motoneuron's response to the chemorepellent Sema-2a, an essential mechanism for the removal of off-target contacts. We have tested an additional Ca-dependent effector, the adenylyl cyclase *rutabaga* (*rut*), and the cAMP phosphodiesterase *dunce*, for their role in synaptic refinement. *rut* and *dnc* mutants both show an elevated frequency of mis-wired, ectopic synapses at the musculature. Using genetic interaction tests we find a functional relationship between cAMP signaling, Ca-channels and semaphorin repulsion for synaptic refinement. We are testing whether cAMP levels must also oscillate for normal synaptic development. We have also analyzed the role of Ca oscillations in embryonic growth cones in vivo using the Ca reporter GCaMP5. In order to suppress movement artifacts we used mutations of the *myosin heavy chain* (*MHC*) gene to suppress muscle contractions, allowing for time-lapse imaging throughout embryonic development. *MHC* embryos show normal muscle development, innervation, and motor system maturation, albeit with fictive motor activity. *MHC* embryos show a progression from activation of single neurons, to synchronous activation of all motoneurons, with late embryos showing coordinated activation of motoneurons in adjacent segments at the same low frequency as in wild type animals. We find that Ca oscillations are observed in both native and ectopic contacts. We are testing the hypothesis that the low frequency Ca oscillations will affect filopodial behavior, possibly through a transient rise in growth cone responsiveness to Sema2a when the Ca levels are high. These results suggest a model for *in vivo* analysis of oscillatory Ca signals in motoneuron synaptic refinement during the formation of neuromuscular junctions.

Abstract: 3-Hydroxykynurenine (3HK) is a metabolite of the kynurenine pathway (KP), which is the main route for tryptophan degradation in mammals. 3-HK is produced from hydroxilation of kynurenine by kynurenine-3-hydroxylase. This metabolite has been widely described as an endogenous cytotoxic agent since it was described as a reactive oxygen species (ROS) generator, and this action was associated with apoptotic cell death in several cell types and models (Eastman and Guilarte, 1989; Nakagami et al, 1996; Okuda et al, 1996). However, this pro-oxidant effect of 3-HK has been discussed and questioned since several evidence showing antioxidant and protective actions of this metabolite (Leipnitz et al, 2007; Backhaus et al, 2008). The aim of this work was evaluated the effect of 3-HK (50 and 100 µM) on ROS production over time (30, 60 90, 120 and 160 min), cell proliferation and cell death (24 h after incubation) in primary astrocytes cultures. Additionally, the effect on ROS production of 3-HK was tested on astrocytes, incubated them with 25 µM of peroxynitrite (ONOO-). In the first 90 min, the 3-HK has no effect on ROS formation, however ROS production was diminished under the control at late times (120 and 160 min) by both concentrations of 3-HK tested. The 3-HK has not effect compare with the control in the cell proliferation evaluated through carboxyfluorescein succinimidyl ester and the cell death determinate by anexin V/propidium iodide assay and lactate dehydrogenase activity. In parallel, both concentrations of 3-HK abolish the ROS production induced by ONOO- in astrocytes primary cultures. These data suggests, that 3-HK exerts an antioxidant action by reducing ROS production even under basal levels and non-compromising primary astrocytes cultures, consequently 3-HK offers strong protection under pro-oxidant insult induced by ONOO- in astrocytes.

Title: Dynamically changing expression patterns of ephrinA/EphA family members in developing hippocampus

Authors: *A. T. HADER, M. R. PLUMMER;
Cell Biol. and Neurosci., Rutgers Univ., Piscataway, NJ

Abstract:
Eph receptors and their ephrin ligands are known to control cell migration, axon guidance, topographic map formation and synaptogenesis in the developing brain. Since ephrin/Eph signaling is bidirectional and based on intercellular interactions, these proteins are potential key molecular players in the development of highly precise neuronal circuits that are crucial for normal brain function. In the hippocampus, Eph receptors and ephrin ligands have been shown to guide layer-specific afferents and regulate synaptogenesis. In ephrin-A5 double knock-out mice, for example, the precision of commissural connections in the inner molecular layer of dentate gyrus is lost, while the final pattern of other commissural connections is not altered. In addition, the density of synaptic contacts is reduced in the target areas of the associative/commissural projections and mossy fibers, but entorhinal synapses don't appear to be affected (Otal et al., Neurosci, 2006). Previous work in our lab showed that ephrinA5 signaling can modulate the function of a synaptogenic molecule, brain-derived neurotrophic factor (BDNF), in rat hippocampal cultures (Bi et al., J.Neurophysiol, 2011). Recently, we have been characterizing the dynamically changing expression patterns of several members of the ephrinA/EphA family to understand better the roles played by these molecules in the specification and maturation of synaptic connectivity. Our data indicate that different EphA receptors and ephrinA ligands show cell type-specific localization patterns that change with developmental stage and appear to be linked to areas of active synapse formation. For example, we and others (Otal et al., Neurosci, 2006) have observed that expression levels of EphA3, one of the receptors for ephrinA5, wax and wane in the target areas of the entorhinal axons yet consistently increase in associative/commissural areas during first month of postnatal development. Additionally, we see that in distinct locations of the developing hippocampus, EphA3 expression generally appears to be presynaptic, suggesting that this receptor might be involved in the process of synaptogenesis. To test explicit hypotheses as to function, we plan to employ molecular tools to knock-down

expression of different ephrinA/EphA family members in a subset of mouse hippocampal neurons and use electrophysiology to assess the involvement of these proteins in coordinating the development of layer-specific connectivity in the hippocampus.

Title: EphA7 splice variants differentially regulate dendritic morphology and synaptogenesis during cerebral cortical development

Authors: *C. LEONARD[1], W. ATHAR[2], M.-S. VAN DER GOES[3], D. BURTON[1], M. DONOGHUE[1];
[1]Georgetown Univ., Washington, DC; [2]Trinity Col., Dublin, Ireland; [3]MIT, Cambridge, MA

Abstract: Intercellular communication is a critical process that regulates the development of neurons, from migration to synaptogenesis. In order to achieve the proper shape and connections, neurons must interact in a variety of ways to determine their fate. One group of molecules, the Eph receptors and their ephrin ligands, play versatile roles in development. EphA7, in particular, has been shown to influence parcellation of brain structures, retinotectal axon guidance, and topographic mapping between the cortex and thalamus. The role of EphA7 in dendritic arborization and synaptogenesis, however, remains unclear.
Our lab has demonstrated that EphA7 is required for multiple stages of neuronal development. When EphA7 is absent from neurons, dendrites can no longer avoid ligand ephrinA5, resulting in altered cell shape. Furthermore, neurons lacking EphA7 are delayed in maturation of synaptic transmission, leading to a decrease in the number of dendritic spines in adults. Therefore, EphA7 is necessary earlier in development, during growth of cellular processes, and later, during the formation and maintenance of neuronal connections. We hypothesize that the distinct roles of EphA7 are subserved by two splice variants of the receptor: a full length form which contains an intracellular tyrosine kinase domain that typically facilitates repulsive signaling between cells; and a truncated form which lacks the kinase domain and is, therefore, incapable of signaling by the same mechanism. Using in vitro and in vivo analyses of murine cortex, we find that full length EphA7 mRNA expression peaks just before birth and decreases throughout adulthood, while truncated EphA7 expression peaks postnatally and remains expressed in the adult cortex.

Gain of function with individual isoforms in wildtype primary cortical neurons produces divergent dendritic morphological changes in culture. Additionally, electrophysiological data from whole-cell recording in acute cortical slices reveal differential synaptic effects when individual isoforms are expressed in EphA7-/- neurons. Our results support a model in which the repulsive, full length EphA7 receptor acts during early neuronal development as a neuron is extending processes to connect with synaptic partners while the permissive truncated EphA7 guides the formation and function of excitatory synapses in adulthood. To our knowledge, this is the first study to investigate the distinct function of the truncated EphA7 receptor since its discovery.

Title: Shank dependent changes in cortical synapse dynamics during neuronal maturation

Authors: *S. A. SPANGLER, L. A. NEEDLEMAN, X.-B. LIU, B. A. MEYERS, A. MCALLISTER;
Univ. of California Davis, Davis, CA

Abstract: Mammalian central nervous system development requires the establishment of trillions of connections between neurons that form the circuits involved in learning, memory, and cognition. A large and growing list of molecules have recently been identified to influence synapse development. Generally, molecules that positively regulate synapse density are posited to affect synapse formation, while those that negatively regulate it are thought to mediate synapse elimination. However, at any given moment, synapse density is dependent on the balance of the creation of new connections and the disassembly of preexisting ones, as well as

the relative stability of each individual synapse. We have designed an in vitro long-term live imaging assay that allows us to observe, quantify, and manipulate developing cortical synapses over periods from hours to days. By expressing fluorescently tagged pre- and postsynaptic proteins in neighboring cultured neurons, we are able to identify sites of synaptic contact in live neurons and follow them over time as synapses are formed, maintained, and eliminated. Using this assay, we have observed that developing synapses are highly dynamic, with fewer than 50% of synapses persisting for more than 90 minutes at 7 days in vitro (div). Though synapses continue to be formed and eliminated into maturity, their stability increases as the neurons mature. By 10div, nearly three-quarters of synapses persist for at least an hour and a half. Shank proteins, which are known to affect synapse density, have pronounced effects on synapse dynamics as well. At 8 div, loss of Shank2 or Shank3 dramatically limits synapse stability while also diminishing both synapse formation and elimination. We are currently investigating whether these effects are similar in other stages of neuronal development, as well as examining exactly how changes in the relative rates of synapse formation and elimination result in changes in synapse density over time.

Abstract: Autism is a highly heritable developmental brain disorder. Mounting evidence suggests that altered synaptic connectivity and function are major causes of autism spectrum disorders (ASDs). A genome-wide-association study identified 3 SNPs near the human *Semaphorin5A* (*SEMA5A*) locus and reported a reduced *SEMA5A* expression in the occipital lobe of autistic brains (Weiss et al., 2009), suggesting that *SEMA5A* is a novel candidate ASD susceptibility gene. Sema5A and its close relative Sema5B are transmembrane proteins characterized by the presence in their ectodomains of a sema domain and a tandem array of seven canonical thrombospondin-type 1 repeats (TSRs). *Sema5A* and *Sema5B* show overlapping, yet distinct, expression patterns in the developing mouse brain and are present in the hippocampus throughout adulthood. To investigate the role played by neuronal *Sema5A*, we analyzed synapse development in the hippocampus using mouse genetics. Ablation of *Sema5A*, but not *Sema5B*, leads to a significant increase in dendritic spine density in both developmentally-born and adult-born dentate granule cells (GCs). Electrophysiological study reveals a significant increase in mEPSC amplitude, but not frequency, in *Sema5A*$^{-/-}$ GCs. At day 21 in culture, *Sema5A*$^{-/-}$ GCs exhibit a greater dendritic spine density than wild type GCs. Expression of recombinant Sema5A rescues the increase in spine number observed in *Sema5A*$^{-/-}$ GC cell-autonomously. We also identified a high-affinity interaction between Sema5A and PlexinA2 *in vitro*. *In situ* hybridization and biochemical data show that PlexinA2 is expressed robustly in the mouse hippocampus. Further, Sema5A and PlexinA2 are both enriched in synaptosomal fractions isolated from the mouse hippocampus. Similar to *Sema5A*$^{-/-}$ mutant mice, *PlexinA2*$^{-/-}$ mice exhibit a significant increase in GC spine density. Furthermore, our functional studies performed in primary GCs show that Sema5A-mediated regulation of dendritic spine density is *PlexinA2*-dependent. The PlexinA2 cytoplasmic domain is necessary for the spine density reduction. Finally, behavioral analysis using the three-chamber test allowed us to identify abnormal social interaction in *Sema5A*$^{-/-}$ congenic mice, suggesting that loss of *Sema5A* leads to a deficit in communication skills, a hallmark of ASD. Therefore, our results support the idea that defects in neuronal cell morphology and synaptogenesis contribute to ASD endophenotypes, identifying a specific guidance cue signaling pathway that may be critical for normal acquisition of social interaction behaviors.

Title: Searching for synaptic connectivity molecules using the *C. elegans* male

Authors: *M. I. LAZARO-PENA, B. KIM, S. W. EMMONS;
Albert Einstein Col. of Med., Bronx, NY

Abstract: How neurons recognize their correct synaptic partners remains largely an unsolved problem. Additional synapse-level connectivity from the new field of connectomics emphasizes the complexity of this process. Our studies of the C. elegans male have defined connectivity among neurons in a neural network that governs mating behavior. The 185 neurons in the network are extensively connected to each other, over a hundred-fold range of strengths, by over 10,000 chemical and electrical synapses. Each neuron makes synapses with many other neurons (average 15-20). Every neuron interacts strongly with some of its partners and weakly with others, forming a smooth distribution from strong to weak. Synaptic partners are similar for equivalent neurons, including the weakly-connected partners—weak connections carry a significant fraction of the load through the network. This indicates that even the weak set of interactions are not random. As male mating is an innate behavior, we conclude that both synaptic partners and strength of interaction are genetically specified. Despite decades of mutational analysis of behavior in C. elegans aimed at dissecting nervous system development and function, only a few genes involved in synaptic connectivity have so far been identified, a seemingly inadequate set to explain the complexity of the male mating network. Therefore, in order to identify additional synapse-specificity molecules, we are taking multiple approaches. Using cell-specific reporter genes that allow us to visualize complex patterns of synapses, we will test the function of candidate genes, blocking their expression by mutation or RNAi. Second, by comparing the transcriptomes of different classes of neurons in single cell-type transcriptome analysis, we hope to identify genes whose expression pattern correlates with particular patterns of connectivity. Third, since the male generates a large number of synapses during a short interval at the end of larval development, we are constructing a time series of the whole-animal transcriptome to identify a set of genes co-expressed at higher levels during this interval. We have shown that increased expression of genes for known synaptic components can be detected at this time and anticipate that still unknown genes for synaptogenesis can be identified by this signature. Finally, we will use reporter genes to compare patterns of connectivity in a set of wild C. elegans strains in hopes of identifying natural variants that can be genetically mapped.

Title: A new automated synaptoneurosome preparation: Comparison between traditional and new techniques

Authors: *J. L. BALSOR[1], K. M. MURPHY[2];
[2]McMaster Integrative Neurosci. Discovery and Study, [1]McMaster Univ., Hamilton, ON, Canada

Abstract: The synaptoneurosome preparation is a popular subcellular fractionation technique that enriches synaptic components and has become a valuable tool for studying synaptic proteins. The traditional technique, developed almost 30 years ago, has not been validated across development or updated to include modern technology. The immature nature of early postnatal cortex, especially in rodents where neurons are still migrating into the cortical plate, growing, and differentiating, raises questions about the consistency of the preparation across ages. We became concerned that the hand homogenization and filtration steps may introduce variability because of the structural immaturity of early postnatal cortex. To address this concern, we compared the traditional hand homogenization and syringe filtration technique with a new technique that we developed using automated tissue homogenization (FastPrep-24, MP Biomedicals) and centrifugal filtration (Ultrafree-MC Centrifugal Filter Tubes, Millipore). We then compared the traditional synaptoneurosome preparation with our new preparation by using Western blots to compare enrichment of synaptic proteins in immature and mature rat cortex. We used synaptic proteins: PSD95 -- a scaffolding protein that anchors glutamate receptors; Gephyrin -- a scaffolding protein that anchors GABA receptors, Synapsin --a marker for pre-synaptic terminals; and Synaptophysin -- a membrane protein on synaptic vesicles. Enrichment was calculated as the ratio between protein expression in synaptoneurosome and homogenate preparations. The updated preparation agreed with previous studies for mature tissue samples, showing consistent two to threefold enrichment. The traditional method produced highly variable enrichment in tissue samples taken from immature cortex. Our new method substantially reduced that variability. These results show the traditional synaptoneurosome preparation is highly variable in early postnatal cortical tissue and could bias interpretation of results. In contrast, our new automated synaptoneurosome preparation produces a consistent level of synaptic protein enrichment in both immature and mature cortical tissue samples.

Title: Segregated innervation and nuclear territories in a polarized cell body during development of the calyx of Held

Authors: *P. S. HOLCOMB[1], M. HOYSON[1], D. R. JACKSON[1], K. MOTWANI[1], B. M. KELLERMEYER[1], M. H. ELLISMAN[2], T. J. DEERINCK[2], G. A. SPIROU[1];
[1]Sensory Neurosci. Res. Ctr., West Virginia Univ. Sch. of Med., Morgantown, WV; [2]Natl. Ctr. for Microscopy and Imaging Res., UCSD, San Diego, CA

Abstract: Cell polarity--both in terms of morphological structure and location of intracellular organelles--plays a vital role in the correct differentiation, migration, and function of eukaryotic cells. In the CNS, defects in proteins vital for the establishment and maintenance of polarity have been implicated in a host of developmental disorders. However, little is known about the role of neuron polarity in synaptogenesis, which may have implications in disorders linked to miswiring such as schizophrenia and autism. To examine the relationship between cell polarity and innervation, we utilized serial block-face scanning electron microscopy (SBEM) and manual three-dimensional reconstruction of the developing calyx of Held and its postsynaptic partner, the principal cell of the medial nucleus of the trapezoid body (MNTB), in the mouse auditory brainstem. This system is ideal for studying the dynamics of synaptogenesis due to the rapid growth dynamics of the calyx (24-48 hours) and a well-defined endpoint of mono-innervation, with each principal cell receiving only a single calyceal input. In order to define nuclear eccentricity, the center of mass (or centroid) of the principal cell and its nucleus were calculated. A plane perpendicular to the vector between these two points and passing through the cell body centroid was used to define distinct somatic “poles”, and the volume of the nucleus contained within each pole was calculated. Similarly, the surface area of the growing calyceal terminal

residing within each pole was determined. This analysis revealed eccentricity in the positioning of the nucleus within the principal cell body, which is present as early as postnatal day 2 (P2) and persists until at least P6. Additionally, preliminary analysis suggests that innervation of the principal cell by potential calyx-forming axons occurs on the somatic surface not containing the nucleus. 3D reconstructions also show a significant wrapping of the principal cell surface by glia at P2, which is removed by P3 preferentially on the non-nuclear pole of the cell. We propose that the position of the nucleus eccentrically within the principal cell body and lack of innervation on this "nuclear pole" is indicative of a polarity-mediated program coordinated between neurons and glia for defining innervation territory for the growing calyceal input. This polarity program may generalize to other model systems in mammals for synaptogenesis during early brain development.

Title: The reduction of latency of action of antidepressants by 17β- estradiol is related to the stimulation of neuronal maturation

Authors: *N. VEGA[1,3], J. FERNÁNDEZ[4], G. RAMÍREZ[2], E. ESTRADA[2];
[1]1Laboratory of Neuropsychopharm., [2]Neuropsychopharm., Natl. Inst. of Psychiatry, México DF, Mexico; [3]Departament of Pharmacobiology, [4]2Departament of Pharmacobiology, Ctr. for Res. and Advanced Studies (CINVESTAV), México D.F., Mexico

Abstract: Several reports indicate that estrogens potentiate the effects of antidepressants and facilitate the action of these drugs by shortening their latency of onset. Estrogens also have a variety of actions on the central nervous system such as the regulation of neuronal excitability, the increase in birth of new cells via the neurogenic process and the synapse formation. Thus, the aim of the present work was to explore if the antidepressant-like effect induced by the

combination of sub-optimal doses of estradiol plus fluoxetine involves changes on cell proliferation, early survival and maturation.
The antidepressant-like effect of the combination of sub-optimal doses of fluoxetine (FLX)-estradiol (E_2) was evaluated in ovariectomized Wistar rats exposed to the forced swimming test (FST, an animal model for the screening of antidepressant drugs). To study the effects of the combination FLX-E_2 on cell proliferation (determined by endogenous marker Ki67), the survival of newborn cells (established with the thymidine analog BrdU; 75 mg/kg, 2/12, i.p before treatment) and on dendrite organization cells (determined by endogenous marker doublecortin), 60 min after the FST the animals were perfused and the brain was dissected. Animals were assigned to one of the following treatments: Vehicle (saline/14 days + Oil/-8h before FST); E_2 (saline/14 days + 10 µg / rat; -8h before of test); FLX (fluoxetine; 5mg/kg/ 14 days + oil/ -8 h before FST), E_2 (saline/14 days + 2.5µg / rat; -8 h before of test); FLX (1.25 mg / kg / 14 days + oil/-8h before to FST) and FLX/E2 (1.25 mg / kg / 14 days+/-8h before to FST).
Results showed that non-effective doses of FLX or E2 given independently did not produce changes on FST or in the number of positive immunoreactivty cells to Ki67, BrdU or doublecortin. In contrast, FLX at dose of 10 mg/kg and estradiol at dose of 10 µg/rat produced an antidepressant-like action in the FST. However, despite of both treatments increased the neuronal maturation, only the FLX also produced changes on cell proliferation and survival. The combination of FLX and E2 at non-effective dose produced an antidepressant-like effect in the forced swimming test and increased the number of new neurons, identified by doublecortin expression, in last phases of dendrite maturation but did not induce changes on cell proliferation or survival.

Title: The role of dynamic microtubules in stabilization of estradiol-induced dendritic spines

Authors: *M. MILLETTE, K. TAYLOR, E. W. DENT;
Neurosci., Univ. of Wisconsin - Madison, Madison, WI

Abstract: Dendritic spines are the major sites of excitatory synaptic transmission in the brain and are widely considered an anatomical substrate for learning and memory. During early development there is a surge in formation and incredible turnover of dendritic spines as functional connections are made with other neurons. In-vivo studies illustrate that many spines may remain stable once formed, but formation and elimination of spines continues throughout adult life. Numerous factors contribute to this plasticity. Notably, estradiol application to cultured neurons is known to increase spine density on a timescale of minutes. Preliminary evidence suggests that estradiol-induced spines are far more transient in nature than previously believed. Using multi-wavelength total internal reflectance fluorescence microscopy (TIRFM) we show a rapid increase in the number of transient dendritic protrusions following estradiol application to mature cortical neurons, but a subsequent disappearance of most protrusions within seconds. Published evidence suggests NMDA receptor activation is involved in stabilizing these estradiol-induced protrusions and estradiol application results in increased PSD-95 at synapse. Our lab has previously shown that microtubules (MTs) directly enter dendritic spines through bouts of dynamic polymerization. We have also shown that MT-invaded spines enlarge in an NMDA receptor- and MT-dependent manner and that synaptic PSD-95 expression following BDNF treatment is dependent on this MT invasion. Therefore, we are currently manipulating MT dynamics and chemically inducing LTP post-E2 in order to probe the role of dynamic MTs in estradiol-induced spine generation and permanency.

Title: Opposing roles of glutamate and neuroligin/neurexin adhesion in cortical synapse formation

Authors: S. L. BARROW[1], *A. MCALLISTER[2];
[1]Ctr. for Neurosci., UC Davis, Davis, CA; [2]Ctr. for Neurosci., UC Davis, DAVIS, CA

Abstract: Formation of synaptic connections is integral to the establishment of the complex circuitry underlying perception, cognition, and behavior. Recruitment of glutamate receptors to nascent synapses is critical to this process. Transport packets rapidly deliver NMDA receptors (NMDARs) to newly forming synapses following initial axo-dendritic contact (Washbourne et al., 2002) via a neuroligin (Nlg)-dependent mechanism (Barrow et al., 2009). Their transport along dendrites occurs bi-directionally , interspersed with frequent pauses at sites where NMDARs cycle with the plasma membrane (Washbourne et al., 2004). Periodic delivery to the dendritic surface raises the possibility that NMDARs are capable of sensing glutamate during their transport, enabling local changes in glutamate secretion to alter their recruitment to newly forming synapses. However, it has been thought that glutamatergic transmission plays no role in synapse formation since synapses can clearly form in the absence of neurotransmitter release (Verhage et al., 2000, Varoqueaux et al., 2002). Using a combination of imaging, electrophysiology and genetic approaches in cultured visual cortical neurons, we sought to determine the role of glutamate and NMDAR activation during the initial establishment of connectivity. Acute pharmacological activation of NMDARs and stimulation with glutamate, globally and locally, decreases the mobility and surface expression of NMDARs, the proportion of mobile NMDARs that are transported with Nlg, and the density of synapses formed. NMDAR blockade has the reverse effect. Moreover, the glutamate-induced decrease in NMDAR transport is dependent on NMDAR-mediated Ca2+ influx. Most important, these effects of glutamate and NMDAR activation are prevented specifically at sites of association of the NMDAR/Nlg complex with neurexin in a mixed co-culture assay. Taken together, these results suggest that glutamate and NMDAR activation play an important role in determining the number of glutamatergic synapses on cortical neurons. Glutamate release appears to regulate synapse formation by destabilizing postsynaptic components that fail to make contact with presynaptic partners, similar to the opposing roles for ACh and agrin at the NMJ.

Title: Molecular mechanisms of electrical synapse development

Authors: *A. MILLER, L. VOELKER, C. MOENS;
Inst. of Neurosci., Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract: Neural circuits, particularly the patterns and properties of their synapses, underlie all behavior. Synapses can either be chemical, where signals are transmitted via neurotransmitter release and reception, or electrical, where signals pass directly through gap junctions between neurons. In order to make circuits, neurons must direct their processes to the correct location, recognize their synaptic partners, and transport proteins to the sites of synaptogenesis. While a number of pathways have been identified that regulate chemical synaptogenesis, the genes that regulate electrical synapse formation are largely unknown.
We are using the zebrafish Mauthner (M) circuit as a model to address electrical synapse formation. The M circuit is made up of individually identified neurons that communicate at unique, stereotyped synapses to generate a fast avoidance turn in response to threatening stimuli. The M neuron is a large interneuron whose cell body is in the hindbrain and whose axon extends contralaterally down the spinal cord. Presynaptic sensory neurons in the ear and lateral line make mixed chemical/electrical synapses on the M cell body and dendrites, and M in turn makes chemical synapses with primary motor neurons and electrical synapses with inhibitory CoLo interneurons in the spinal cord. A forward genetic screen looking for mutations that disrupt M electrical synapses identified two classes of mutations: Disconnect (Dis, 3 alleles) in which electrical synapses are reduced or absent and Amped (Amp, 2 alleles) in which supernumerary electrical synapses form. These phenotypes suggest that there are positive (Dis genes) and negative (Amp genes) regulators of electrical synapse formation.
To identify the genes disrupted in the mutants we have employed a novel RNA-seq-based mapping pipeline and have found a nonsense mutation in the autism-associated gene neurobeachin (nbea) in Dis4 mutants. A TALEN induced lesion in nbea does not complement Dis4 confirming that nbea is causal for the electrical synapse defect. Nbea is a highly conserved, multidomain protein that is implicated in synaptic protein trafficking in neurons. Using chimeric analysis in which a limited number of cells are mutant in an otherwise wildtype animal we have found that Nbea is required in the postsynaptic neuron for electrical synapse formation. Our findings suggest that Nbea regulates the transport of proteins necessary for postsynaptic, but not presynaptic, electrical synapse formation.

Title: Crystal structures of the C1q-like protein family reveal conserved Ca2+ binding motifs crucial for BAI3 GPCR interaction and synapse homeostasis

Authors: *S. RESSL[1], D. C. MARTINELLI[1], B. K. VU[1], T. C. SÜDHOF[1,2], A. T. BRUNGER[1,2];
[1]Stanford Univ., Stanford, CA; [2]HHMI, Stanford, CA

Abstract: Background C1q-like (C1ql) are secreted proteins of yet unknown function belonging to the C1q/TNF super-family. Recent findings show that a) C1ql proteins are expressed in neurons (1) and have Ca^{2+} dependent affinity for the brain-specific angiogenesis inhibitor 3 (BAI3) G-protein coupled receptor (GPCR) (2). These findings suggest a role for C1ql in synapse homeostasis. Here we describe the crystal structure of the globular C1q domains of C1ql1-3, and residues involved in Ca^{2+}-dependent binding to BAI3. We characterize the specific structural and functional differences within the C1ql family and propose a functional role as specific regulators in synapse homeostasis via Ca^{2+}-dependent binding to BAI3. **Methods** We used X-ray crystallography to determine the crystal structures of the C1ql protein family. Based on the structures, we mutated a series of specific ion binding residues. The structural integrity and stability of purified C1ql proteins and mutants was verified by CD-spectroscopy. We measured the Ca^{2+} binding affinity of C1ql proteins and mutants to elucidate differences in ion binding observed in the structures using isothermal calorimetry. Fluorescence labeled cell-surface binding assays and biolayer interferometry were used to characterize C1ql and mutants binding to BAI3. Furthermore we employed neuronal culture experiments to study C1ql and mutants effect on synapse number and dendrite growth in cultured neurons. **Results** The crystal structures of C1ql proteins reveal structural and ion-binding differences within the family and reveal conserved Ca^{2+} binding motifs essential for BAI3 receptor binding. Whereas the crystal structures of C1ql1 and C1ql3 show ion-binding regions, the structure of C1ql2 does not. A specific arginine residue conserved in C1ql2 across species replaces positive charged ions observed in C1ql1 and C1ql3 at the identified Ca^{2+}-dependent BAI3 binding site. Because C1ql2 and C1ql3 can form hetero-trimers in the brain (1), the difference in ion binding properties of C1ql proteins suggests a regulatory element of receptor binding specificity in dependence of Ca^{2+} ion concentration. C1ql3 mutants show decreased structural stability and a loss in BAI3

receptor binding. C1ql3 mutants also vary from wildtype C1ql3 in their effect on synapse homeostasis in cultured neurons. **Conclusions** The presence of the Ca^{2+} binding motifs is crucial for BAI3 receptor binding. We suggest that C1ql proteins play an important regulatory role in synapse homeostasis in specific regions of the brain by binding to BAI3.

Title: PirB is a receptor for LGI1 and alters seizure progression in mice

Authors: *R. A. THOMAS[1], C. X. Q. CHEN[1], V. SOUBANNIER[1], S. BAULAC[2], P. A. BARKER[1];
[1]CNS, Montreal Neurolog. Inst. McGill Univ., Montreal, QC, Canada; [2]CRICM UPMC, Hôpital de la Pitié-Salpêtrière, Paris, France

Abstract: LGI1 is the first non-ion channel protein to be identified as causative in epilepsy in humans: a mutation in a single allele results in autosomal dominant lateral temporal lobe epilepsy. We previously identified LGI1 as a novel ligand for Nogo Receptor 1 (NgR1), a GPI-linked protein that was initially identified as a receptor for myelin-derived neuronal growth inhibitors (MGIs). NgR1 has also been shown to restrict synaptic plasticity during critical period closure and memory retention in the CNS. A structurally unrelated receptor, termed PirB, has likewise been implicated in restricting activity-dependent synaptic plasticity as well as functioning as a receptor for MGIs.
Intriguingly, we have recently found that PirB is a high affinity receptor for LGI1 and demonstrated that NgR1 and PirB are associated in a cell surface complex when expressed in heterologous cells. Identification of this receptor complex led us to ask if NgR1 and PirB have a role a in seizure progression in mice. Complete loss of LGI1 function in mice results in spontaneous seizure activity and death, LGI1-/+ mice do not have spontaneous seizures but do have a reduced threshold for seizure induction. We tested whether mice rendered null for NgR1 or for PirB, have a reduced threshold for seizure induction and found that deletion of either gene results a reduced seizure threshold.
Our results indicate that NgR1, PirB and LGI1 could interact in the formation of neural circuitry

involved in seizure progression. Recently, both NgR1 and LGI1 have been shown to regulate synaptic refinement in different contexts and we are currently investigating the effect of LGI1 and NgR1 on synapse formation and maintenance within central nervous system neurons.

Title: Sema4D signaling in mammalian CNS GABAergic synapse development

Authors: *A. R. MOORE, M. S. KUZIRIAN, A. J. RASSI, S. PARADIS;
Brandeis Univ., Waltham, MA

Abstract: While there are a number of molecules known to mediate glutamatergic synapse development, relatively few molecules have been identified as mediators of GABAergic synapse development. We have previously identified the transmembrane protein, Semaphorin4D (Sema4D) as an important regulator of GABAergic synapse formation, using a forward genetic RNAi-based screen. Semaphorins are a family of proteins that are implicated in a number of cellular processes including axon guidance, T cell activation, angiogenesis and recently, synapse development. However, the exact function of Sema4D and the receptor through which it signals to regulate GABAergic synapse formation remains unknown. To address this question, we first constructed multiple chimeras of Sema4D, including a non-cleavable form, by replacing different domains of Sema4D with that of the transmembrane protein CD4, a small single pass protein involved in T-cell activation. This approach revealed that Sema4D signals through its extracellular domain as a membrane-bound protein localized to the synaptic membrane in mammalian hippocampus. From this result, we then went on to examine the function of Sema4D in mediating GABAergic synapse formation by utilizing a combination of immunocytochemistry and electrophysiology in cultured hippocampal neurons and acute hippocampal slice treated with the functional, extracellular Sema domain from Sema4D. We found that treatment of cultured neurons with the extracellular domain of Sema4D causes a rapid increase (i.e. 30 minutes) in GABAergic synapse density (as assayed by immunocytochemistry) accompanied by an increase in miniature inhibitory postsynaptic current frequency within 2 hours (as assayed by whole-cell

voltage clamp recordings). Importantly, Sema4D treatment was unable to drive GABAergic synapse development when these experiments were performed on neurons isolated from mice in which the putative Sema4D receptor PlexinB1 had been constitutively deleted. These data strongly suggest the Sema4D is capable of rapidly initiating functional GABAergic synapse development in a PlexinB1-dependent manner.

Title: A point mutation abolishes presynaptic targeting of the synaptic vesicle protein mover

Authors: A. AKULA, F. WETZEL, A. PETKOVA, J. HOEBER, T. GHELANI, N. WITTENMAYER, *T. DRESBACH;
Univ. of Goettingen, Goettingen, Germany

Abstract: Synapses are asymmetric cell-cell contacts.Targeting of synaptic vesicles to presynaptic sites is one of the most intricate examples of polarized trafficking and site-specific accumulation. Suprisingly little is known about amino acid sequences or strucutral requirements mediating presynaptic targeting of synaptic vesicles proteins. Here we have characterized presynaptic targeting of Mover / TPRGL / SVAP30, a 266 amino acid protein associated with synaptic vesicles as a peripheral membrane protein. We used expression of GFP-tagged versions of Mover in cultured hippocampal neurons as a screening system, testing which recombinant variants of Mover undergo presynaptic targeting. We found that deleting either of 4 predicted phosphorylation sites did not impair targeting. By contrast, introducing a phenylalanine to arginine mutation into a c-terminal area of Mover completely abolished presynaptic targeting, leading to a diffuse distribution of the mutant protein. To delineate the domain mediating targeting we expressed several deletion constructs. However, neither an n-terminal region, a c-terminal region nor a central region allowed for targeting. These deletion constructs also failed to dimerize, as revealed in co-immunoprecipitation assays. A yeast-2-hybrid assay, and co-immunoprecipitation corroborated the strong tendency of Mover to undergo homomeric interaction. These data suggest that Mover forms dimers or oligomers as a prerequisite for a

phenylalanine residue to become exposed and mediate association with components of the axonal trafficking machinery.

Title: The Wrb gene encodes a novel protein required for ribbon synapse function

Authors: *L. L. DANIELE[1], F. EMRAN[2], B. PERKINS[3];
[1]Ophthalmic Res., Cole Eye Inst., Cleveland, OH; [2]Ctr. for Res. in Neurosci., McGill Univ., Montreal, QC, Canada; [3]Ophthalmic Res., Cole Eye Institute, Cleveland Clin., Cleveland, OH

Abstract: Ribbon synapses of sensory neurons tonically release glutamate to signal graded changes in stimulus intensity. The ribbon structure tethers numerous synaptic vesicles in close proximity to the presynaptic active zone, and is composed mainly of the scaffolding protein ribeye. The zebrafish *hi1482* mutant was isolated with defects in vision and mechanosensory signaling. The mutation results from a retroviral insertion in a gene encoding the novel protein, tryptophan rich basic protein (Wrb).The objective of this study was to investigate the *wrb* mutant to gain insight into the role of this novel protein in ribbon synapse structure and function. Electroretinography (ERG), Immunohistochemistry (IHC) and electron microscopy (EM) analyses were employed to assess ribbon synapse function, protein expression, and ultrastructure. w*rb* mutants were crossed with transgenic fish expressing membrane-tethered YFP in ON bipolar cells, Tg(nyx:mYFP), to investigate the morphology of ON bipolar cell contacts. *wrb* mutants at 5 dpf had diminished cone - derived ERG b-waves, which arise from ON bipolar cells. Cone derived a-waves had normal amplitudes. The mechanosensory hair cells of the lateral line organ had severely decreased FM143 staining, consistent with a defect in vesicle release. Ribeye localization was disrupted in *wrb* mutants, having a diffuse distribution pattern at synapses of photoreceptors and lateral line hair cells. EM analysis revealed a decrease in the number of presynaptic ribbons, with ribbons frequently found floating in the synaptic cytoplasm. Synaptic vesicle protein 2 (SV2) was also mislocalized, consistent with evidence of disrupted ribbon assembly. Preliminary evidence also suggested disrupted expression of the presynaptic

calcium channel subunit, CaV1.3a, in hair cell synapses. Despite disrupted ribbon synapse structure, the post-synaptic contacts of bipolar cells and horizontal cells at cone synaptic terminals were structurally normal in *wrb* mutants, with no aberrant contacts detected in YFP labeled bipolar cells.
The attenuated synaptic transmission at ribbon synapses and the mislocalization of key presynaptic components in the *wrb* mutant suggests that Wrb is important for the assembly or maintenance of ribbon synapses. Interestingly, retinal cone photoreceptors maintained appropriate contacts with post-synaptic neurons, despite the reduced transmission in the mutants, suggesting that the maintenance of synaptic contacts may not depend on synaptic release, or that residual synaptic function is sufficient.

Title: Slow, stable, and long-distance retrograde movement of synaptophysin-positive puncta along axons in corticospinal slice coculture

Authors: *N. YOSHIOKA, N. ISOO, N. MURABE, H. KAMEDA, I. TAKAHASHI, M. SAKURAI;
Dept. Physiol., Teikyo Univ. Sch. Med., Tokyo, Japan

Abstract: Synapse formation requires transport of presynaptic components along the axons to the target area. Synaptic vesicles are transported and accumulated at presynaptic sites. In organotypic corticospinal slice coculture system, we used EGFP-tagged synaptophysin (Syp-EGFP) as a marker for presynaptic vesicles and tried to capture the whole sequence of events that proceed along the axons in the target tissue. By way of in vitro electroporation, we labeled cortical cells with Syp-EGFP and monitored the dynamic properties of the distribution of the protein along the axons. We also introduced DsRed2 to visualize axonal morphological change at the same time. To perform time-lapse imaging of the fluorescence signals from those corticospinal axons in static slice coculture, we developed a system using a custom made stage top CO_2 incubator equipped to a non-inverted confocal microscope stage. This CO_2 incubator can take a dry objective lens without having condensation. This system allows us to image

fluorescence signals repeatedly at the interval of 5-60 min for more than 10 hours under ordinary static culture condition for brain slices kept on a membrane culture insert. We found that, at already 2 days in vitro (2 DIV), Syp-EGFP signal was accumulated to form puncta. Those puncta were associated with axonal swellings or varicosities visualized by DsRed2. Unexpectedly, when time-lapse image acquisitions were made at an interval of 60 min, those puncta showed slow (10-50 μm/hour, a hundred times slower than the rate previously reported), continuous, stable and long-distance (sometimes exceeding 300 μm) movement along the axons. Puncta movements coincided with varicosity movements and were dominantly retrograde at all the culturing days examined (2-7 DIV). In cases movements lasted for more than 3 hours at a constant rate, they were sometimes interrupted by elongated pauses for more than 1 hour. The movements were also monitored at 5 min intervals and rates of constant movement comparable to that monitored at 60 min intervals were obtained, which further supported continuous and stable movement. The frequency of puncta to show movement in 6 hours was 30 % at 3 DIV and declined gradually until 7 DIV with a frequency of less than 10 %. As the time point of 7 DIV coincides with that of synaptogenesis in the corticospinal slice coculture, we hypothesized that those migrating puncta are a type of prepared packages for presynaptic apparatus, searching for potential synaptic sites and cease their movement when captured by those sites.

Title: CaMKII phosphorylation of neuroligin-1 regulates excitatory synapses

Authors: *M. A. BEMBEN[1], S. L. SHIPMAN[2], T. HIRAI[1], R. A. NICOLL[2], J. S. DIAMOND[1], K. W. ROCHE[1];
[1]NINDS, NIH, Bethesda, MD; [2]Cell. and Mol. Pharmacol., Univ. of California, San Francisco, San Francisco, CA

Abstract: Neuroligins are postsynaptic cell adhesion molecules that are important for synaptic function through their transsynaptic interaction with neurexins. The localization and synaptic effects of neuroligin-1 are specific to excitatory synapses with the capacity to enhance excitatory synapses dependent on synaptic activity or Ca2+/CaM Kinase II. Here, we report that Ca2+/CaM

Kinase II robustly phosphorylates the intracellular domain of neuroligin-1 but not neuroligin-3. We show that T739 is the dominant CaMKII site and is phosphorylated in response to synaptic activity in neurons. Furthermore, a phospho-deficient mutant (T739A) reduces the basal and activity-driven surface expression of neuroligin-1, leading to a reduction in neuroligin-mediated excitatory synaptic potentiation. Therefore we report the first direct functional interplay between CaMKII and neuroligin-1, two primary components of excitatory synapses.

Title: Role of neurolastin, a novel brain-specific GTPase, in regulating excitatory synapses and spine morphology

Authors: *R. M. LOMASH, W. LU, R. J. YOULE, K. W. ROCHE;
NINDS, Natl. Inst. of Hlth., Bethesda, MD

Abstract: Glutamate receptors mediate the majority of excitatory neurotransmission in the mammalian nervous system. The precise regulation of the levels of these receptors at synapses is the underlying mechanism mediating synaptic plasticity. Processes such as membrane trafficking and post-translational modifications including ubiquitination tightly regulate the number of neurotransmitter receptors available at any given time. Key players regulating membrane trafficking events include GTPases of the dynamin superfamily that hydrolyze GTP to steer membrane fusion events. Recently, a novel brain-specific GTPase was discovered in the Roche lab, which was named neurolastin (RNF112/Znf179) because it is most closely related to the dynamin superfamily GTPase, atlastin. Neurolastin also has a RING finger domain (typically found in E3 ligases, that mediate ubiquitination) and is the first identified protein with a unique domain organization harboring both GTPase and RING domains, yet there have been no reports in the literature that either annotate its GTPase domain or demonstrate its GTPase or E3 ligase activity. Here, we demonstrate that neurolastin has the ability to hydrolyze GTP to mono-phosphate (GMP) and the GTPase activity is involved in the maintenance of dendritic spine density. We observed that expression of neurolastin leads to an increase in the density of

dendritic spines on hippocampal neurons, whereas expression of the GTPase activity mutant (R340Q) did not affect the spine density demonstrating the role of neurolastin's GTPase activity in maintenance of spine density. Subsequently, we also observed a significant decrease in the frequency of mEPSCs in hippocampal slices from knockout mice indicating a marked reduction in the number of functional synapses in the absence of neurolastin. These results suggest that neurolastin affects synaptic plasticity by regulating synaptogenesis and spine maintenance. This work was initiated by Stephanie McNeil as part of her doctoral thesis at Johns Hopkins University.

Title: A novel role for AIDA-1 in regulating NMDA receptor subunit composition and long-term potentiation

Authors: *J. O. TINDI, A. E. CHÁVEZ, S. CVEJIC, P. E. CASTILLO, B. A. JORDAN; Dominick P. Purpura Dept. of Neurosci., Albert Einstein Col. of Med. of Yeshiva Univ., Bronx, NY

Abstract: The NMDA subtype of ionotropic glutamate receptors (NMDARs) plays important roles in neurotransmission, synaptic plasticity, learning, memory and behavior. NMDARs are heterotetramers composed of two obligate GluN1 subunits together with GluN2 (A-D) and/or GluN3 (A-B) subunits, which confer specific channel properties. GluN1:GluN2A:GluN2B heteromers comprise the majority of NMDARs in the hippocampus, and the ratio of GluN2B to GluN2A subunits is developmentally regulated. How these subunits contribute to NMDAR function and higher order brain functions is unclear despite considerable efforts exploring this question. AIDA-1 (amyloid precursor protein intracellular domain associated -1) is widely expressed in the CNS, binds directly to the postsynaptic scaffolding protein PSD-95 and is present in complexes with NMDARs. Here we show that AIDA-1 is in complex with GluN2B but not GluN2A-containing NMDARs in the hippocampus. Acute knockdown of AIDA-1 in rat dissociated hippocampal neuronal cultures using lentivirally delivered shRNAs results in

decreased GluN2B subunit expression at synapses with a concomitant increase in GluN2A expression. We have also generated forebrain specific (using CaMKIIα-Cre mice) AIDA-1 conditional knockout mice (AIDA-1 cKO) to study the role of AIDA-1 *in vivo*. We find that Schaffer collateral to CA1 pyramidal neuron (Sch-CA1) synapses in these mice display normal basal AMPA receptor (AMPAR)-mediated transmission and no change in NMDAR/AMPAR current ratio. However, the NMDAR-EPSC decay time is reduced in AIDA-1 cKO mice, suggesting an alteration in the subunit composition of synaptic NMDARs. In addition, NMDAR-EPSCs in these mice shows reduced sensitivity to the GluN2B-specific antagonist Ro 25-6981, consistent with decreased GluN2B, increased GluN2A or both. Biochemical fractionation experiments reveal increased GluN2A and decreased GluN2B subunits in hippocampal postsynaptic densities from AIDA-1 cKO mice and no changes in GluN1 or other ionotropic glutamate receptors. The alteration in GluN2A/GluN2B expression ratio occurs without a change in total subunit abundance, suggesting a defect in NMDAR trafficking. Consistent with the critical role of NMDARs in synaptic plasticity, Sch-CA1 LTP is significantly impaired in AIDA-1 cKO mice. Moreover, AIDA-1 cKO mice exhibit deficits in memory-dependent tasks such as object placement recognition. Together, our findings support a novel synaptic role for AIDA-1 in the regulation of NMDAR composition at synapses with consequences for plasticity and behavior.

Title: A novel functional role of STEP in regulating phosphorylation of the synaptic GluN2B via PSD-95 association

Authors: *S. WON, K. W. ROCHE;
NIH/NINDS, NIH/NINDS, Bethesda, MD

Abstract: NMDA receptors (NMDARs) are a subtype of ionotropic glutamate receptors that play a key role in synaptic plasticity, neuronal development, learning and memory. They are functional tetramers composed of two GluN1 subunits, two GluN2A-D and GluN3 subunits.

Particularly, GluN2 subunits define many of the functional properties of the channel, their trafficking, and their synaptic expression. While the C terminus of GluN2B subunit of NMDARs contains a clathrin adaptor protein (AP-2) binding site and endocytic motif YEKL, GluN2A does not have the same motif. Many reports about tyrosine phosphorylation in the endocytic motif of GluN2B have revealed that this tyrosine phosphorylation affects surface expression of GluN2B-containing NMDARs. The tyrosine 1472 residue (Y1472) within the YEKL motif of GluN2B is phosphorylated by the Src family of kinases (SFKs). Particularly Fyn, a member of SFKs, can phosphorylate the Y1472 of GluN2B and the phosphorylation of Y1472 inhibits the binding of AP-2, thereby promoting surface expression of GluN2B-containing NMDARs. The phosphorylation of NMDARs by Fyn is promoted by postsynaptic density-95 (PSD-95), a member of membrane-associated guanylate kinase family of proteins (MAGUKs) that is well-known for binding to PDZ binding domain (ESDV) in the GluN2 subunits of NMDARs. Striatal-enriched protein tyrosine phosphatase (STEP) is a brain-specific intracellular tyrosine phosphatase. STEP has two representative isoforms, which are targeted to different intracellular compartments. $STEP_{46}$ is a cytosolic isoform, whereas $STEP_{61}$ is a membrane-associated isoform that localizes to the endoplasmic reticulum and the postsynaptic density. STEPs regulate ERK 1/2, p38, Fyn kinases and also GluN2B. STEP dephosphorylates ERK 1/2, p38, and Fyn kinases at their regulatory tyrosine residues, thereby inactivating them. In the case of GluN2B, STEP dephosphorylates Y1472 in its endocytic motif and facilitates the internalization of NMDARs including GluN2B subunits. However, the precise mechanism regulating the dephosphorylation of Y1472 in GluN2B by STEP is not understood. We have characterized the two isoforms and find a distinct subcellular localization in the rat brain and this implies they have different roles within the cell and at different developmental stages. We have also investigated the specificity of $STEP_{61}$ binding to a variety of MAGUKs and again find specificity of $STEP_{61}$ compared to $STEP_{46}$. The PDZ3 domain of PSD-95 binds to $STEP_{61}$ but not $STEP_{46}$. Interestingly, $STEP_{61}$ can also bind directly to the NMDARs. These results reveal the complexity of $STEP_{61}$ interactions with PSD-95 and NMDARs.

Title: Specificity Protein 4 functionally regulates the transcription of NMDA receptor subunits GluN1, GluN2A, and GluN2B

Authors: *A. PRIYA, K. JOHAR, M. T. T. WONG-RILEY;
Cell Biology, Neurobiology, and Anat., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: N-methyl-d-aspartate (NMDA) receptors are major glutamatergic receptors involved in most excitatory neurotransmission in the brain. The transcriptional regulation of NMDA receptors is not fully understood. Previously, we found that the GluN1 and GluN2B subunits of the NMDA receptor are regulated by nuclear respiratory factors 1 and 2 (NRF-1 and NRF-2). NRF-1 and NRF-2 also regulate all 13 subunits of cytochrome c oxidase (COX), a critical energy generating enzyme, thereby coupling neuronal activity and energy metabolism at the transcriptional level. Specificity Protein (Sp) is a family of transcription factors that bind to GC-rich regions, with Sp1, Sp3, and Sp4 all binding to the same cis motifs. Sp1 and Sp3 are ubiquitously expressed, whereas Sp4 expression is restricted to neuronal and testicular cells. Recently, we found that the Sp factors regulate all subunits of COX. The goal of the present study was to test our hypothesis that the Sp factors also regulate specific subunits of NMDA receptors, and that they function with NRF-1 and NRF-2 via one of three mechanisms: complementary, concurrent and parallel, or a combination of complementary and concurrent/parallel. By means of multiple approaches we found that Sp4 functionally regulates GluN1, GluN2A, and GluN2B, but not GluN2C. On the other hand, Sp1 and Sp3 did not regulate these subunits as previously thought. Our data indicate that Sp4 operates in a complementary as well as a concurrent and parallel manner with NRF-1 and NRF-2 to mediate the tight coupling between energy metabolism and neuronal activity at the molecular level. Title: Identifying interacting regions between the GluN subunits & the Src anchoring protein ND2 in the NMDAR complex

Authors: *D. SCANLON, H. L. LEDUC-PESSAH, M. W. SALTER;
Neurosciences and Mental Hlth., The Hosp. For Sick Children, Toronto, ON, Canada

Abstract: Upregulation of NMDA receptors (NMDARs) by the tyrosine kinase Src is critical for long-term potentiation of synaptic transmission in the hippocampus & chronic pain hypersensitivity in the spinal cord. Src is anchored in the NMDAR complex by ND2, NADH dehydrogenase subunit 2, which functions as an adaptor protein. The primary sequence requirements for the interaction between Src & ND2 have been determined, but the interacting regions between ND2 & the GluN subunits have been elusive. To elucidate the basis for this interaction, we transfected HEK293 cells with GFP-tagged ND2 or GFP-ND2 fragments, with GluN subunits or receptor controls. We assessed the correlation between the ND2 constructs and the GluN subunits/controls by confocal microscopy. Thresholded Pearson's Correlation Coefficient (PCC) was used as a measure of colocalization. GFP-ND2 differentially colocalized with GluN1/GluN2A NMDARs (PCC = 0.61±0.03) as compared with AMPARs (0.19±0.03), P2X4Rs (0.30±0.03), actin (0.10±0.02) or PSD95 (0.28±0.03) (one-way ANOVA $p<0.001$). GFP-ND2 also differentially colocalized with GluN1 alone (0.66±0.02) as compared with GluN2A (0.03±0.03). Additionally, GFP-ND2 colocalized with a GluN1-C-terminal deletion mutant (0.65±0.03) and a GluN1 C and ATD (Amino Terminal Domain) deletion mutant (GluN1ΔCΔATD) (0.61±0.02). The ND2 fragment 150-347 (0.66±0.03) also colocalized with GluN1 alone, but the ND2 fragment 250-347 did not (0.33±0.04). Subsequently, we found that ND2-150-240 colocalized with GluN1 alone (0.78±0.02) and with both GluN1 + GluN2A (0.66±0.02) and GluN1ΔCΔATD + GluN2A (0.70±0.03). Thus, we have determined that GluN1, but not GluN2A, is necessary and sufficient for colocalization with ND2, and that the C-tail and amino terminal domain of GluN1 are dispensable. Furthermore, we have identified a 91 amino acid region of ND2 that is sufficient to interact with the core of the NMDAR complex.

Title: *In vitro* exposure to nicotine modulate the function of presynaptic NMDA receptors present on dopaminergic terminals in rat Nucleus Accumbens

Authors: *M. MARCHI[1], A. SALAMONE[1], S. ZAPPETTINI[1], M. GRILLI[1], G. OLIVERO[1], R. CUNHA[2], A. PITTALUGA[1];
[1]Dept. of Pharm., Univ. of Genova, Genova, Italy; [2]Univ. of Coimbra, Coimbra, Portugal

Abstract: Here we provide functional and immunocytochemical evidence supporting the presence on Nucleus Accumbens (NAc) dopaminergic terminals of N-methyl-D-aspartic acid (NMDA) receptors colocalized with nicotinic acetylcholine receptors (nAChRs). Immunocytochemical studies showed that a significant percentage of NAc terminals were dopaminergic and that most of these terminals also posses nAChRs which contain the α4 subunit. The in vitro short-term pre-exposure of synaptosomes to 30 µM nicotine or 5IA85380 caused a significant reduction of both the 30 µM nicotine and the 100 µM NMDA-evoked [^{3}H]Dopamine (DA) overflow. This reduction was completely counteracted when synaptosomes were pretreated with nicotine plus mecamylamine. In synaptosomes transiently stimulated with 100 µM NMDA before and after pretreatment with 100 µM nicotine or 10 nM 5IA85380 the time course of FURA-2 AM fluorescence emission changes shows a significant decrease of the NMDA-evoked calcium transients. The inhibitory effect of 5IA85380 was completely counteracted when synaptosomes were pretreated in the presence of the selective antagonist DHβE indicating that the changes of the NMDA-dependent DA release reported was dependent to the activation of a β2* nAChR subtype. The NMDA-evoked overflow was almost completely antagonized in presence of MK801 and partially inhibited in presence of the non specific antagonist CGS-19755 and by RO 25-6981 and Ifenprodil, two specific GluN2B antagonists. CPP-19755 and $ZnCl_2$ (1 nM), two compounds showing preferring affinities at GluN2A subunits did not antagonized the NMDA effect. A significant decrease in GluN2B biotin tagged proteins was observed following exposure of NAc synaptosomes to nicotine pretreatment when compared to control.. Therefore, our results show that the NMDA receptor function can be dynamically and negatively regulated in neurons in response to a brief incubation with nAChRs agonists.

Title: N-Methyl-D-aspartate receptor is expressed by rat cultured cortical astrocytes and regulates their mitochondrial membrane potential

Authors: P. MONTES DE OCA BALDERAS[1], *P. AGUILERA[2], A. SANTAMARIA[1];
[1]Aminoacidos Excitadores, Inst. Nacional de Neurologia y Neurocirugia, Mexico, Mexico;
[2]Patologia Vascular Cerebral, Inst. Nacional de Neurologia y Neurocirugia, Mexico Distrito Federal, Mexico

Abstract: Astrocytes were conceived traditionally only as structural cells in the CNS. However, their gliotransmitter secretion, neurotransmitter receptor expression, and network properties provided the basis to support their role in information processing and cognitive functions. Ionotropic glutamate N-methy D-aspartate receptor (NMDAR) is critical in CNS functions including learning, memory and cognition. Nonetheless, NMDAR expression and functionality in astrocytes is still under research and debate. In this work, we investigated NMDAR subunit expression in rat cultured cortical astrocytes (rCCA) through immunofluorescence. Our observations demonstrate NMDAR subunits NR1, NR2A and NR2B labeling in GFAP positive cells with intracellular distribution characteristic of transmembrane molecules. Consistently, NMDAR subunit mRNA synthesis was found by qRT-PCR. Western Blot experiments with two different Abs flanking NR1 N-and C- terminal domains, the critical subunit for NMDAR assembly and transport, revealed its full length synthesis. Since these results indicated NMDAR expression in rCCA, we further assayed NMDAR functionality through time-lapse experiments evaluating astrocyte's mitochondrial membrane potential ($m\Delta\psi$) in response to NMDA using the ratiometric sensor JC-1. We found that NMDA treatment reduced $m\Delta\psi$, although cell-by-cell analysis revealed some response heterogeneity. NMDA effect on $m\Delta\psi$ was inhibited by NMDAR inhibitor MK-801 and accompanied by iCa++ rise measured with Fluo-4-AM. Altogether, these results demonstrate that rCCA express NMDAR subunits that are assembled into functional membrane receptors that after activation mediate extracellular Ca++ entry that diminishes $m\Delta\psi$. These observations open the possibility to use rCCA to study putative posttranslational modifications in NMDAR subunits.

Abstract: Among the cellular mechanisms required for modifications of dendritic spines, synapse-to-nucleus communication plays a key role in the regulation of the long-term structural changes. Emerging evidence indicates that multiple signalling pathways arising from dendritic spines converge to the nucleus regulating the expression of genes associated with changes of synapto-dendritic inputs. In the last decade, few synapto-nuclear protein messengers have been identified, and shown to play key roles in plasticity and synapse function. We recently identified Ring Finger Protein 10 (RNF10) as a new synapse-to-nucleus molecule, which responds to specific calcium signals at the postsynaptic compartment to elicit discrete changes at the transcriptional level. RNF10 is highly enriched at the excitatory synapse where it is associated to the GluN2A subunit of NMDA receptors. RNF10 is also present in the nucleus, where it is known to associate with Mesenchyme Homeobox 2 (Meox-2) transcription factor. Activation of synaptic NMDA receptors leads to RNF10 translocation from dendritic spines to the nucleus and induction of the expression of RNF10 target genes. Interestingly, modulation of RNF10 expression levels plays a fundamental role in regulating excitatory spine morphology under resting conditions as well as following activity-dependent synaptic plasticity.

Title: Mechanisms of synaptic NMDA receptor potentiation by Wnt5a

Authors: A. MCQUATE[1], *A. BARRIA[2];
[1]Physiol. & Biophysics - NEUBEH Program, [2]Physiol. & Biophysics, Univ. of Washington, SEATTLE, WA

Abstract: Wnts are secreted glycoproteins that signal through canonical and noncanonical pathways to organize synapses in the adult nervous system. Wnt5a specifically and acutely potentiates NMDA receptor transmission at the hippocampal CA3-CA1 synapse. The potentiation requires intracellular calcium, PKC, and JNK kinases. The precise mechanisms leading to larger NMDAR current amplitudes, however, remain unknown. We hypothesized that Wnt5a facilitates trafficking of NMDA receptors into the synapse. We found the increase in NMDAR currents after Wnt5a application is dependent on SNAP-25, a member of the SNARE family of membrane fusion proteins. Using two-photon fluorescence microscopy and optically tagged NR2 subunits of the NMDA receptor, we are further testing whether Wnt5a induces surface expression or surface redistribution of NMDA receptors. Overall, our results support the hypothesis that Wnt5a can regulate glutamatergic synapses in the adult nervous system by governing NMDA receptor trafficking. This novel role for Wnt signaling could have profound consequences in regulating both basal synaptic transmission and plasticity.

Title: Effects of polyamines and monoamines on GluN1/GluN2A and GluN1/GluN2B subtypes of NMDA receptor

Authors: *Y. YAMADA[1], K. NORIKANE[1], K. MATSUMARU[2], H. IZU[2];
[1]Dept of Biotech and Chem Fac of Engin. Kinki Univ., Higashi-Hiroshima, Japan; [2]Natl. Res. Inst. of Brewing, Higashi-hiroshima, Japan

Abstract: NMDA-type glutamate receptors (NMDA receptors) are widely distributed in the central nervous system and play critical roles in synaptic plasticity and excitotoxicity. Dysfunctions of NMDA receptors are involved in several central nervous system disorders, including stroke, chronic pain and schizophrenia. There are a few NMDA receptor antagonists available for clinical use, including ketamine and most importantly, mematine, both of which act as channel blockers. Mematine is used for Alzheimer's disease.Polyamines, such as putrescine, spermine and spermisine, are poly basic aliphatic amines that were ubiquitously present in prokaryotic and eukaryotic cells. Extracellular polyamines have multiple effects on NMDA receptors. Spermine is known to inhibit or activate the channel activity of NMDA receptor subunits dependent manner.
Only NMDA receptors containing the GluN2B subunits display polyamine potentiation. The study of the channel block activity with the polyamine derivative is applied to a study of the structure activity correlation of the receptor, development of the brain function or improvement medicine. Wine, sake, cheese, and other fermented foods are known to contain various polyamines and monoamines. Junmai shu (Japanese sake made from rice only) contains several amines (agmatine, spermine, putrescine, tyramine, isoamylamine, and 2-phenylethylamine). Some of them have not investigated about their physiological activity. So, we examined the effect of six amines on GluN1/GluN2B and GluN1/GluN2A subtypes of NMDA receptors, which were expressed in *Xenopus* oocytes. Agmatine, putrescine, tyramine, and 2-phenylethylamine inhibited the activity of both receptors. 2-phenylethylamine especially inhibited the activity of both receptors.
Isoamylamine indicated the opposite effect of spermine. It was indicated that isoamylamine act as an antagonist against the GluN1/GluN2B receptor, but an activator for GluN1/GluN2A receptor. Observed differences in activity between the receptor subtypes, it may be able to elucidate the mechanism of action of amines on the NMDA receptor channel. It was indicated the possibility that activator amines used as medicines for mental illness, such as schizophrenia and antagonistic amines used as potential therapeutic agents such as anxiety and dementia.

Title: NMDAR-mediated EPSCs in single pyramidal neurons are highly dependent on a concomitant rise in peri-synaptic pH

Authors: H.-Y. CHEN[1], *M. CHESLER[2];
[1]Dept. of Physiol. & Neurosci., NYU Sch. of Med., New York, NY; [2]Dept. of Neurosurg., Dept. Neurosurg. NYU Sch. of Med., New York, NY

Abstract: Synchronous neural activity elicits a population extracellular alkaline transient (PAT) due to proton – Ca^{2+} exchange of the plasma membrane Ca^{2+} ATPase (PMCA). Previous work on hippocampal CA1 pyramidal neurons (PNs) indicated that a PAT boosts the NMDAR-mediated component of EPSCs elicited via the Schaffer collaterals, presumably due to relief of the constitutive proton block of these receptors (1). There was no such effect on the AMPAR component of the current (2,3). Whether this modulation of post-synaptic NMDARs occurs with more discrete activity is unknown. To test this idea we blocked the PAT with DNQX plus picrotoxin (to shut down all population activity) and evoked pure NMDAR-mediated EPSCs in single PNs clamped at +50 mV. Increasing effective buffering capacity with exogenous carbonic anhydrase (xCAR) decreased the EPSC peak by 32 $\pm$ 3.3 percent (N=8 cells) with no change in time course. xCAR caused similar reduction of EPSCs at holding potentials of +50 versus –30 mV, and did not alter EPSC reversal potential. The effect of adding xCAR was: (i) blocked by benzolamide, an inhibitor of extracellular carbonic anhydrase, (ii) mimicked by 20 mM HEPES in standard Ringer, and (iii) was fully occluded by HEPES in standard Ringer. These data indicate that the effect of xCAR was due to pH buffering, and required the enzyme active site. Given that buffering can reduce, but not abolish a peri-synaptic pH change, our results indicate that post-synaptic NMDAR current of a single CA1 PN is highly dependent on a self-generated rise in peri-synaptic pH. These data further suggest that the PMCA, due to its inward transport of protons, can paradoxically boost Ca^{2+} entry via NMDARs, despite its more general, evolved role as a mechanism of cytosolic Ca^{2+} clearance. Title: Subunit-selective glun2c and glun2d nmda receptor potentiators reverse mk801-induced impairment of pre-pulse inhibition

Authors: *K. STRONG[1], K. K. OGDEN[2], R. M. SANTANGELO FREEL[1], D. LIOTTA[1], L. G. CHASTAIN[3], B. KINKEAD[3], S. F. TRAYNELIS[2];
[1]Chem. Dept., [2]Pharmacol. Dept., [3]Psychiatry and Behavioral Sci., Emory Univ., Atlanta, GA

Abstract: NMDA receptors mediate a slow, Ca^{2+}-permeable component of excitatory synaptic transmission. One leading hypothesis concerning the basis of schizophrenia postulates that NMDA receptor hypofunction underlies certain clinical features of the disease. This hypothesis has led to the prediction that NMDA receptor potentiators could have therapeutic benefit for treatment of schizophrenia. We recently reported a new class of GluN2C/D-selective potentiators built on a tetrahydroisoquinoline core. Here we describe in detail the structure-activity relationship around this series. We also report stereoselective actions of several members of this class of potentiators. We further show that these potentiators are more effective at low agonist concentrations. Analysis of off-target activity and brain penetration (brain:plasma ratio of >2) supports the use of these compounds in animal models that are relevant for schizophrenia. We therefore evaluated whether a prototypical member of this class (CIQ) could rescue deficits of pre-pulse inhibition (PPI), a measure of sensorimotor gating, caused by the use-dependent NMDA channel blocker MK801. Compared to controls (19.5% PPI), we find robust disruption of PPI by 0.2 mg/kg (sc) MK801 (4.1% PPI) that is significantly relieved by administration of 20 mg/kg CIQ i.p (14.8% PPI, n=14-15, $p<0.05$ ANOVA). These data support the idea that NMDA receptor potentiation might have utility in treatment of schizophrenia, and further highlight GluN2C/D subunits as important contributors to the effects of MK801 on PPI

Abstract: N-methyl-D-aspartate receptors (NMDARs) are heterotetrameric ligand-gated ion channels implicated in learning and memory, as well as in a variety of neuropsychiatric disorders including schizophrenia and Alzheimer’s disease. NMDARs are gated by the neurotransmitter glutamate and are positively modulated by endogenous hydrophobic allosteric ligands including pregnenolone sulfate (PS) and arachidonic acid (AA). Recently, we have discovered a novel endogenous NMDAR positive allosteric modulator, the major brain cholesterol metabolite 24(S)-hydroxycholesterol (24(S)-HC). We have also shown that the synthetic oxysterol derivative [$\Delta^{5,6}$-

3β-Oxy-nor-cholenyl]-dimethyl-carbinol (SGE-201) similarly modulates NMDAR function. Here we investigate additional mechanistic aspects of oxysterol regulation of NMDARs. These oxysterols exhibited no selectivity for the major NMDAR GluN2 subunits (GluN2A, B, C, D), suggesting a broad spectrum of action. Potentiation was observed in subsaturating and saturating concentrations of glycine, suggesting that oxysterol potentiation does not involve interaction with co-agonist. Oxysterol modulation also did not depend on NMDA concentration, suggesting that potentiation is associated with an increase in agonist efficacy. In tests of shared mechanism we found that SGE-201 and 24(S)-HC exhibit occlusion, yet oxysterols did not occlude potentiation by PS or by the membrane-derived phospholipid, AA. Another endogenous oxysterol, 25-hydroxycholesterol did not potentiate NMDAR activity but occluded modulation by SGE-201. This suggests possible competition among different endogenous cholesterol metabolites and excludes shared actions of oxysterols (e.g., membrane disordering effects) in NMDAR potentiation. Although intracellular access could participate in oxysterol actions, SGE-201 potentiation required extracellular access, suggesting an extracellular binding site. Intracellular application of SGE-201 to neurons was ineffective. In excised outside-out patches, SGE-201 potentiated channel activity without significantly altering channel conductance, also consistent with a direct action on NMDAR channel gating. Our data demonstrate that 24(S)-HC and the structurally-related oxysterol SGE-201 act through a previously undescribed mechanism and are unusual among positive allosteric modulators of ligand-gated ion channels in regulating agonist efficacy without appreciable effects on channel closing rate.

Title: Network pharmacodynamics of the NMDAR channel blockers memantine and ketamine

Authors: *C. M. WROGE[1,2], L. N. EISENMAN[3], Y. IZUMI[1,5], J. J. DOHERTY[6], S. M. PAUL[7], C. F. ZORUMSKI[1,5], S. MENNERICK[1,4,5];

Abstract: Memantine and ketamine, activation dependent blockers of the NMDA receptor, have markedly different properties clinically. Mild pharmacodynamic differences at steady-state have been suggested to participate in clinical differences, but it is unknown whether these differences are evident during non-steady state agonist presentation and transient depolarization that characterize physiological activity. We previously found no difference between memantine and ketamine, except that memantine exhibits slightly faster re-equilibration following depolarization. Consistent with the suggestion that this biophysical difference plays little role under physiological conditions, the drugs were indistinguishable when network activity was measured as spontaneous EPSCs or using a multi-electrode array. At low micromolar concentrations and with acute application 15 prior to induction, both drugs also selectively inhibited LTD but not LTP in hippocampal slices, again denoting essential similarity under dynamic conditions. We were only able to discern a slight but statistically significant difference between the drugs in their neuroprotection against hypoxic insult. We hypothesize that these drugs do not escape the channel during EPSPs in part because of the weak gating efficacy of the NMDAR channel. We manipulated channel gating efficacy by chelating Zn2+ at GluN2A-containing receptors or with the synthetic oxysterol analogue: δ5,6-3β-Oxy-nor-cholenyl]-dimethyl-carbinol (SGE-201). Both treatments increased the rate constant of drug re-equilibration upon depolarization. For instance, SGE-201 decreased memantine (10 μM) steady-state block at -70 mV (96 ± 0.7% to 92 ± 1%, $p<0.05$) and reduced the weighted time constant for drug re-equilibration at +50 mV from 1293 ± 250 ms to 384 ± 45 ms ($p<0.05$, N=11). SGE-201 also enhanced separation between the neuroprotective effects of ketamine and memantine, consistent with our biophysical observations. We conclude that differences in voltage dependence between the two drugs are masked by the inherently low gating efficacy of the NMDA receptor, which is unusual among ligand-gated channels. Under baseline conditions the drugs act essentially voltage independently over the time course of EPSPs.

Title: The major brain cholesterol metabolite 24(S)-hydroxycholesterol is a potent allosteric modulator of N-methyl-D-aspartate receptors

Authors: *S. M. PAUL[1,2], J. J. DOHERTY[2], A. J. ROBICHAUD[2], G. BELFORT[2], B. Y. CHOW[2], D. C. CRAWFORD[3], A. J. LINSENBARDT[3], Y. IZUMI[3], S. MENNERICK[3], C. F. ZORUMSKI[3];
[1]Appel Alzheimer's Dis. Res. Inst., New York, NY; [2]Sage Therapeut., Cambridge, MA; [3]Washington Univ. Sch. of Med., St. Louis, MO

Abstract: N-methyl-D-aspartate receptors (NMDARs) are glutamate-gated ion channels that are critical to the regulation of excitatory synaptic function in the CNS. NMDARs are essential for

experience-dependent synaptic plasticity and have also been implicated in the pathophysiology of various neuropsychiatric disorders including the cognitive deficits of schizophrenia and Alzheimer's disease as well as certain forms of autism. NMDARs are modulated by a number of endogenous substances including Mg^{2+} and the co-agonists glycine and D-serine. Certain neurosteroids have been shown to modulate NMDARs experimentally, both *in vitro* and *in vivo*, but their low potency and very low brain concentrations make them poor candidates as endogenous ligands. We now report that the major brain-derived oxysterol 24(S)-hydroxycholesterol (24(S)-HC) is a very potent and selective positive allosteric modulator of NMDARs. At nanomolar to low micromolar concentrations, well below that present in brain, 24(S)-HC potentiates with unusually slow kinetics NMDAR-mediated EPSCs in mouse hippocampal neurons but fails to affect AMPAR or GABA-AR-mediated responses. Cholesterol itself and other naturally-occurring oxysterols present in brain do not modulate NMDARs at concentrations ≤ 10 μM. Modulation appears to involve a direct effect on NMDARs rather than second-messenger signaling or transcription, as NMDAR potentiation is evident in excised outside-out membrane patches. In hippocampal slices, 24(S)-HC enhances the ability of subthreshold stimuli to induce long-term potentiation (LTP), a form of synaptic plasticity underlying learning and memory. 24(S)-HC also prevents a deficit in LTP induction triggered by transient application of low micromolar ketamine that persists for several hours following ketamine washout. Finally, we show that two synthetic drug-like derivatives of 24(S)-HC (SGE-201 and SGE-301) which potently enhance NMDAR-mediated-EPSCs and LTP via an overlapping if not identical oxysterol modulatory site, reverse memory impairment induced by a NMDAR antagonist in mice. 24(S)-HC is synthesized from cholesterol by cholesterol 24-hydroxylase a cytochrome P450 enzyme (CYP46A1) expressed primarily in brain and localized to the endoplasmic reticulum of neuronal cell bodies and dendrites. Consequently, 24(S)-HC may function as an endogenous autocrine modulator of NMDARs acting at a novel oxysterol modulatory site that also represents a potential target for therapeutic drug development.

Title: A novel class of positive allosteric NMDA receptor modulators

Authors: *R. E. PERSZYK[1], B. M. KATZMAN[2], D. C. LIOTTA[2], S. F. TRAYNELIS[1]; [1]Pharmacol., [2]Chem., Emory Univ., Atlanta, GA

Abstract: N-methyl-D-aspartate (NMDA) receptors are ionotropic ligand-gated ion channels that are activated by glutamate and glycine and mediate a slow component of excitatory synaptic currents in the central nervous system. These receptors play important roles in synaptic plasticity, neuronal development, and have been implicated in a number of neurological disorders. The enhancement of NMDA receptor-mediated currents has been hypothesized to confer cognitive enhancement and could be potentially beneficial in correcting discrepancies in schizophrenia. Testing these hypotheses has been limited due to a lack of highly potent and effective pharmacological compounds. We have identified a number of structurally distinct classes of NMDA receptor allosteric modulators through a screen of 100,000 compounds. During the structure-activity relationship development of one of these classes of negative allosteric modulators (typified by compound 1794-1) we discovered a series of substitutions on the molecule that converted these negative allosteric modulators into positive allosteric modulators. Using two-electrode voltage clamp recordings of NMDA receptors expressed in *Xenopus oocytes*, we have studied several of these related NMDA receptor potentiators and found that they can enhance responses 150-250% with EC_{50} values ranging from 2 to 10 μM (n=10-14). Co-application of positive and negative modulators in this class suggests that the positive modulators can compete with the negative modulators. This raises the possibility that both positive and negative modulation of NMDA receptors by this class of molecules occurs through actions at a single site. This class of compounds could be utilized to assess the validity of enhancing NMDA receptor activity as a potentially beneficial strategy in neuropsychiatric disorders, and could lead to the development of drug-like pharmacological compounds targeting these strategies.

Title: The pre-M1 region of GluN2 subunits is a critical gating element of NMDA receptors

Authors: *K. K. OGDEN, J. ZHANG, S. F. TRAYNELIS;
Pharmacol., Emory Univ., ATLANTA, GA

Abstract: Glutamate receptor ion channels, which include AMPA receptors, kainate receptors, and NMDA receptors, mediate the majority of excitatory synaptic transmission in the central nervous system. A fundamental question is how these ligand-gated ion channels transduce binding of the amino acid glutamate into opening of the ion channel pore. X-ray crystallographic data from a tetrameric AMPA receptor revealed a short 7 residue "cuff" helix in the pre-M1 region of the receptor that is situated parallel to the lipid bilayer and may act a critical structural determinant of channel gating by restricting movement of pore-forming transmembrane helices until agonist binds. Whether a similar element exists in NMDA receptors and what its role in gating is remains unknown. Using cell-attached patch clamp, we recorded single-channel currents from NMDA receptors containing mutations in the pre-M1 region of GluN2A. Mutations at several residues in the pre-M1 region to alanine or to the homologous residue in the GluN2D subunit reduced channel open probability. The most dramatic changes occurred with 2A(L550A), which reduced open probability from 0.12 ± 0.05 (control, n=7) to 0.0012 ± 0.0003 (n=7). Open durations were described by a mixture of two exponential distributions with $\tau 1$=1.54 ms (area=74%) and $\tau 2$=0.12 ms for control. The fitted time constants were markedly shorter in 2A(L550A), with $\tau 1$=0.55 ms (area=66%) and $\tau 2$=0.10 ms. These data suggest the pre-M1 region of GluN2A is critical for normal gating of NMDA receptors. The pre-M1 region of GluN2D was recently implicated in the actions of the GluN2C/2D-selective positive allosteric

modulator CIQ. Thus, understanding how the pre-M1 region impacts gating of NMDA receptors may reveal new mechanisms for regulation of the receptor by endogenous and exogenous modulators and interacting proteins.

Title: A novel class of negative allosteric modulators of NMDA receptor function

Authors: *B. M. KATZMAN[1], R. E. PERSZYK[2], D. C. LIOTTA[1], S. F. TRAYNELIS[2]; [1]Chem., [2]Pharmacol., Emory Univ., Atlanta, GA

Abstract: The N-methyl-D-aspartate receptor (NMDA receptor) is an ionotropic glutamate receptor that mediates a slow component of excitatory synaptic transmission. Under normal situations, NMDA receptors are involved in many neurological processes including learning and memory. NMDA receptor dysfunction has been implicated in several neuropathological conditions, such as Parkinson's disease, Alzheimer's disease, and neuronal damage during ischemia. Therapeutic agents acting at NMDA receptors have been proposed for treating disorders, but in most cases side effects have complicated the clinical evaluation. In an effort to identify new modulators of NMDA receptors, we screened a library of compounds against GluN1/GluN2C- and GluN1/GluN2D-expressing BHK cells. Identification of two screening hits (compound 1794-1 and 1794-2), lead to the development of a novel class of inhibitors that have a modest preference for GluN2C/D receptors. These compounds are noncompetitive inhibitors of

NMDA receptor function, as their actions are not surmounted by increasing the concentration of glutamate or glycine (n=4-6 for all). Additionally, evaluation of the current-voltage curve showed that inhibition was voltage-independent for 1794-2 (3 μM, n=5), suggesting these compounds do not block the open channel. Interestingly, multiple members of this class of compounds cause sub-maximal inhibition even at saturating concentrations in two-electrode voltage clamp recordings of *Xenopus oocytes* expressing recombinant receptors. We have shown one member of this series (1794-2) is active in neurons, inhibiting NMDA receptor function in cerebellar granule cells with an IC_{50} value (3.5 μM, n=2-5) similar to that at recombinant GluN2A- and GluN2B-containing recombinant receptors (1 μM n=18, 3 μM n=12, respectively). Compound 1794-2 also shows neuroprotective properties against NMDA-induced toxicity in primary neuronal cultures (n=2). This class of compounds could be useful neuroprotective agents in stroke or neurodegenerative diseases, with their partial antagonism potentially diminishing undesirable side effects.

Title: Modulation of glycinergic NMDA receptors by protons and zinc

Authors: *K. A. CUMMINGS, G. K. POPESCU;
Biochem., Univ. At Buffalo, Buffalo, NY

Abstract: Glycinergic N-methyl-D-aspartate receptors (NMDARs) differ from the traditional glutamatergic NMDARs in that that they are insensitive to glutamate and can be activated by glycine alone. They assemble as combinations of eight GluN1 (NR1) splice variants (1a through 4b) and two GluN3 (NR3) isoforms (A and B). NR1/NR3 receptors have smaller unitary conductance, lower Ca2+ permeability, and decreased sensitivity to voltage-dependent Mg2+

block. Zinc and hydrogen ions are endogenous modulators of synaptic transmission and are strong allosteric inhibitors of classical NMDARs. Here we investigated the effects of zinc and hydrogen ions on GluN1-4a/GluN3A (NR1/NR3A) receptors. We found that in contrast to classical NMDARs, protons potentiated glycine-elicited NR1/NR3A receptor currents ~ 2-fold (Imax ~ pH 6.8), and also decreased the rate and extent of their desensitization. At physiological proton concentrations (pH 7.4), zinc ions (50 uM) inhibited the glycine-elicited current by ~60% and this effect was absent at pH 6.8. The zinc effects we observed differ from previously reported strong potentiation by zinc in glycinergic receptors assembled from the NR1-1a splice variant. Because the 1a and 4a splice variants only differ in the intracellular C-terminal tail, taken together with known spatiotemporal expression of the NR1 splice variants, these results suggest a possible intracellularly-governed response to extracellular zinc that may be brain region-specific. Additionally, these results indicate that under both physiological and pathological conditions, NR1/NR3A receptors function on a broad spectrum of activity. Increased activity of these receptors under periods of low pH such as stroke indicates that these receptors may play a larger role in ischemic events than previously known, making NR1/NR3A receptors a viable drug target.

Title: Development of NMDA receptor-dependent glutamate excitotoxicity in human embryonic stem cell-derived neurons: An *In vitro* model system

Authors: *K. GUPTA[1,2], G. E. HARDINGHAM[3], S. CHANDRAN[2];
[1]MRC Lab. for Regenerative Med., Univ. of Cambridge, Cambridge, United Kingdom; [2]Ctr. for Neuroregeneration, [3]Ctr. for Integrative Physiol., Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Increasing evidence implicates the role of glutamate-mediated excitotoxic neuronal death in the pathogenesis of a range of neurological disorders. Neuronal excitotoxicity is principally mediated by the NMDA-subtype glutamate receptor (NMDAR), though other pathways have been implicated. Evidence suggests that the subunit composition of NMDARs is critical for downstream signaling, and as such physiological patterns of synaptic glutamate transmission can be neuroprotective, while aberrant glutamate transmission can result in neuronal death. Human based experimental systems, specifically human pluripotent stem cells, have the potential to further elucidate pathways relevant to human neurological diseases and identify novel therapeutic targets. In this study, we utilize human embryonic stem cells (HESC) to generate an enriched population of neurons and characterize the development of functional glutamate responses and vulnerability to glutamate excitotoxicity. We demonstrate that HESC-derived neurons progressively developed functional glutamate responses attributable to NMDAR activity over two months in culture, concomitant with increasing expression of NMDAR and AMPAR receptor subunit mRNA. Moreover, differentiated human neurons exhibited dose-dependent glutamate-mediated cell death within the range of glutamate concentrations found in human patients suffering acute brain injury. NMDAR antagonists varied in efficacy; MK801 significantly reduced excitotoxic neuronal death. The NR2B-selective antagonist ifenprodil did not significantly reduce neuronal excitotoxic cell death. Interestingly, NMDA alone did not recapitulate the full excitotoxic effect of glutamate in this system. These data highlight the complexity of NMDAR and excitotoxic signaling, and demonstrate the utility of a human in vitro platform for enhancing the clinical translation of findings made in complementary systems. Furthermore, this study provides important proof-of-concept that HESC-derived neurons can be used effectively to model glutamate-mediated neurotoxicity and test candidate therapeutic compounds, and can potentially inform future studies in other human pluripotent systems such as induced pluripotent stem cells.

Title: Kinetics and pharmacology of triheteromeric nmda receptors at hippocampal synapses

Authors: *K. R. TOVAR[1], G. L. WESTBROOK[2];
[1]Vollum Inst., Vollum Inst., PORTLAND, OR; [2]Oregon Hlth. and Sci. Univ., Vollum Inst., Portland, OR

Abstract: The majority of NMDA receptor activation occurs at synapses. The transient nature of quantal neurotransmitter presentation and elimination imposes specific macroscopic behavior on the resulting excitatory postsynaptic current (EPSC), which is governed by the subunit composition of synaptic receptors. NMDA receptors are tetrameric proteins composed of GluN1 and GluN2 subunits, in a 1 to 1 ratio. NMDA receptor functional heterogeneity results from developmental and anatomical expression patterns of GluN2 subunits. Additionally, many neurons in the mammalian central nervous system express more than one GluN2 subunit, leading to the possibility of three NMDA receptor subtypes at synapses. In mouse hippocampal neurons expressing GluN2A and GluN2B, most synaptic NMDA receptors contain both GluN2 subunits, along with GluN1 (Tovar et al., 2013). In isolation, these receptors have kinetic and pharmacological properties that are distinct from diheteromeric receptors containing GluN2A or GluN2B. GluN2A and GluN2B are the most highly expressed GluN2 subunits in the mammalian brain and thus synaptic triheteromeric receptors with distinct properties may be more prevalent than previously appreciated. The amino-terminal domains (NTDs) of GluN2 subunits, in large measure, defines subunit-dependent properties. NTDs are the binding sites for ligands such as zinc or ifenprodil which modulate NMDA receptor gating behavior. Ligand interaction with these domains prolong the activation of NMDA receptor-mediated EPSCs in diheteromeric receptors. This results from an increase in the channel dwell time in agonist-bound, nonconducting states (Tovar and Westbrook, 2012). In wild-type neurons, zinc or ifenprodil reduced the EPSC amplitude of isolated triheteromeric receptors containing GluN2A and GluN2B (AB-type receptors). However zinc prolonged EPSCs whereas ifenprodil did not. Thus the effect of ifenprodil on AB-type EPSCs compares to that of a competitive antagonist rather than a gating modulator. The dichotomy of effectiveness between NTD ligands is interesting in terms of screening therapeutics that modulate NMDA receptor kinetic behavior. To extend these observations, we are investigating whether other phenylethanolamine compounds cause prolonged activation of NMDA receptor-mediated EPSCs in isolated triheteromeric receptors, as well as how they affect gating in the non-equilibrium environment. This work could address why phenylethanolamine compounds have thus far, not proven successful as clinical therapeutics and point toward a more effective drug discovery strategy.

Title: MHC class I is a voltage-dependent regulator of NMDA receptor-mediated single-channel currents

Authors: *C. M. TYLER[1], M. CHACON[1], J. I. AGUILAR[1], D. H. PERLMAN[1], L. FOURGEAUD[2], L. M. BOULANGER[1];
[1]Dept. of Mol. Biol. and Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ; [2]Div. of Biol. Sciences, Section of Neurobio., Univ. of California at San Diego, La Jolla, CA

Abstract: Proteins of the major histocompatibility complex class I (MHC class I) are known for their role in the immune response, and were recently identified as endogenous regulators of excitatory synaptic transmission. In hippocampal CA1 pyramidal neurons from MHC class I-deficient ($\beta2M^{-/-}TAP^{-/-}$) mice, whole-cell currents mediated by NMDA-type glutamate receptors (I_{NMDAR}) are significantly enhanced, while currents mediated by AMPA-type glutamate receptors are unaffected. The increase in whole-cell I_{NMDAR} in MHC class I-deficient brain is not associated with changes in the levels, localization, or subunit composition of NMDARs, or in the number of AMPAR-free ("silent") synapses (Fourgeaud *et al.*, 2010). Thus the cellular mechanisms by which MHC class I regulates whole-cell I_{NMDAR} remain unknown. One key question is whether MHCI affects NMDAR-mediated currents equally across a range of postsynaptic membrane potentials. We find that whole-cell I_{NMDAR} is selectively enhanced at depolarized membrane potentials (+40 mV), but not at hyperpolarized potentials (-70mV), in MHC class I-deficient mice, consistent with the idea that MHC class I does not affect NMDAR expression or trafficking, but rather might influence NMDAR single-channel behavior. To test if MHC class I regulates NMDAR single-channel properties, we estimated NMDAR unitary current using non-stationary noise analysis (NSNA). This method, unlike conventional single-channel recording, allows direct estimation of the behavior of synaptically-localized receptors. NSNA of evoked currents shows that NMDAR unitary currents are significantly enhanced in MHC class I-deficient neurons relative to WT. This single-channel enhancement is also only observed at depolarized membrane potentials, and is sufficient to explain the increase in whole-cell current in MHC class I-deficient animals. MHC class I does not form a stable macromolecular complex with the obligatory GluN1 subunit in brain lysates, suggesting that MHC class I affects NMDAR single-channel properties through one or more signaling

intermediates. Ongoing studies are exploring the effects of MHC class I on post-translational modification of GluN2 subunits, a possible source of changes in unitary currents. Thus MHC class I is a voltage-dependent brake on NMDAR single-channel currents at the synapse. These results clarify a mechanism by which changes in MHC class I expression, like those seen with brain injury, stroke, infection, and aging, might affect the risk of NMDAR-mediated excitotoxicity.

Title: Charged residues external to the NMDA receptor gate control gating and conductance

Authors: *B. A. MAKI[1], G. K. POPESCU[2];
[1]Biochemistry, Neurosci., Univ. At Buffalo, SUNY, Buffalo, NY; [2]Biochem., SUNY Buffalo, Buffalo, NY

Abstract: Critical to N-methyl-D-aspartate receptor (NMDAR) functions are the receptor's high Ca2+ permeability, high unitary conductance and characteristically slow kinetics. So far, two molecular determinants of Ca2+ permeability have been identified, both of which are located on the obligatory GluN1 subunit: 1) the asparagine residue situated at the narrow constriction of the channel pore, and 2) a cluster of charged residues within the DRPEER motif, which is located just extracellular to the agonist controlled gate. In the related AMPA receptors, residues located in this latter region control receptor activation and desensitization kinetics. To investigate whether these residues also control single-channel properties of NMDARs, we examined cell-attached currents recorded from GluN1/GluN2A receptors that had single alanine substituted for the charged residues within the DRPEER region. Receptors with alanine substitutions at negatively charged residues (D640A, E643A and E644A) had shorter mean open times (MOTs), whereas R641A, had a ~2-fold longer MOT. Surprisingly, these mutants also had altered conductance and this correlated positively (R2 = 0.9462) with changes in open durations.

Further, we ascertained that the effects on both conductance and gating were conferred by charge ablation, since isosteric mutations (D640N, R641Q) resulted in phenotypes similar to the alanine mutants, whereas introducing charged residues that differed in size (D640E, R641K) produced currents that were indistinguishable from wild-type traces. These results demonstrate that in addition to controlling Ca2+ permeability, residues within the DRPEER also control channel conductance and receptor gating properties. In addition, the correlation we uncovered between open durations and conductance may help investigations into the mechanisms that govern properties of NMDARs that are critical to normal synaptic development and plasticity but also with glutamate excitotoxicity.

Title: Synaptic-like glutamate applications reveal NMDA receptor subtype-dependent inhibition by memantine and ketamine

Authors: *N. G. GLASGOW, J. W. JOHNSON;
Dept. of Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: NMDA receptors (NMDARs) are tetrameric ionotropic glutamate (glu) receptors usually composed of 2 GluN2 subunits, of which there are 4 types (A-D), and 2 GluN1 subunits. NMDAR subtype is defined by the GluN2 subunits present (e.g. GluN1/2A receptors contain GluN1 and GluN2A subunits). NMDAR properties such as maximal Popen and deactivation kinetics vary by NMDAR subtype. NMDARs are found at most vertebrate excitatory synapses as well as extrasynaptically and are essential to the normal function of the nervous system. Inhibition of NMDARs by open channel blockers has broad potential for treatment of pathological conditions: for example, memantine is approved for treatment of Alzheimer's disease, and ketamine has shown promise in treatment of both depression in patients resistant to other treatments and of neuropathic pain in preclinical models. Although memantine and ketamine share similar kinetics and IC50s at NMDARs, their clinical effects vary significantly,

suggesting that their mechanisms of NMDAR inhibition may differ in ways that are not yet well understood. Previous studies have shown that during long applications of glu, neither memantine nor ketamine shows selectivity between GluN1/2A and GluN1/2B receptors, which contain the subunits thought to predominate at synaptic sites in cortex. However, it was recently demonstrated in neuronal cultures that memantine inhibits synaptic NMDAR currents less effectively than currents activated by long agonist applications (Xia et al., 2010), suggesting that duration of agonist exposure may influence inhibition by memantine and perhaps inhibition by open channel blockers in general. To examine this hypothesis, we measured inhibition by memantine and ketamine as a function of glu application duration and of NMDAR subtype. We performed whole-cell recordings from tsA201 cells transfected to express either GluN1/2A or GluN1/2B receptors, and simulated synaptic glu release using a fast perfusion system optimized to apply glu to lifted cells for ~5 ms. We compared inhibition by memantine and ketamine of synaptic-like glu applications and of long (> 10 s) glu applications. We found that memantine inhibits synaptic-like GluN1/2A, but not GluN1/2B, receptor currents less effectively than responses to long applications. Ketamine also inhibits synaptic-like GluN1/2A receptor currents less effectively than responses to long applications, but inhibits synaptic-like GluN1/2B receptor currents more effectively than responses to long applications. Thus, synaptic-like applications of glu reveal a blocker- and NMDAR subtype-dependence not observed with long glu applications.

Title: Sites of alcohol action at the GluN1/GluN2B NMDA receptor M3-M4 domain intersubunit interfaces

Authors: Y. ZHAO, M. WU, H. REN, *R. W. PEOPLES;
Biomed. Sci., Marquette Univ., MILWAUKEE, WI

Abstract: The N-methyl-D-aspartate (NMDA) receptor has been shown to be one of the most important target sites of alcohol in the central nervous system. We and others have identified positions in the third and fourth membrane-associated (M) domains of both GluN1 and GluN2A subunits that influence alcohol sensitivity. In the structural model of the NMDA receptor based

upon the related GluA2 receptor, the outward face of the M3 domain of one subunit type is oriented toward the M4 domain of the other subunit type. We recently reported that four pairs of alcohol-sensitive amino acid positions in GluN1/GluN2A NMDA receptors interact at the M3-M4 intersubunit interfaces with respect to alcohol sensitivity and receptor kinetics. Because a number of studies point to a major role for the GluN2B subunit in the action of alcohol in the brain, in the present study we used site-directed mutagenesis and electrophysiological patch-clamp recording in transfected cells to investigate the sensitivity of cognate positions in the GluN2B subunit, as well as interactions between positions in the M3 and M4 domains of the GluN1 and GluN2B subunits affecting ethanol inhibition. Although the M3 and M4 domains of GluN2A and GluN2B are highly conserved, only one of four positions in GluN2B, F637, corresponding to alcohol-sensitive positions in GluN2A exhibited altered ethanol IC_{50} values in substitution mutants. However, we observed interactions with respect to ethanol sensitivity among three out of four pairs of positions (G638/M824, F639/L825, and M818/F637 in GluN1/GluN2B), even when single substitution mutations at one of the two positions in a pair (GluN1 M818; GluN2B M824, L825) had no effect on alcohol sensitivity. These results support the existence of sites of alcohol action formed by clusters of positions at the M3-M4 domain intersubunit interfaces of GluN1/GluN2B NMDA receptors, although they appear to differ from the corresponding sites in GluN1/GluN2A receptors reported previously.

Title: Extrasynaptic NMDA receptors on fast-spiking prefrontal cortical interneurons

Authors: *E. M. LEWIS[1], P. O'DONNELL[2];
[1]Anat. & Neurobio., Univ. of MD Baltimore, Baltimore, MD; [2]Anat. & Neurobio., Univ. of MD, Baltimore, Baltimore, MD

Abstract: Disinhibited cortical circuits are central to current views of schizophrenia pathophysiology. Non-competing NMDA receptor antagonists, known to be psychotomimetic in adults, have been proposed to exert their effect primarily by blocking receptors on fast-spiking interneurons (FSI) yielding increased pyramidal cell activity. Reductions in NMDA signaling

early in development, either globally using pharmacological approaches or specifically in parvalbumin (PV) positive interneurons have been shown to lead to behavioral and electrophysiological phenotypes resembling phenomena observed in schizophrenia patients (Belforte et. al, 2010). However, it has been recently demonstrated that the contribution of NMDA receptor activation to excitatory postsynaptic potentials (EPSP) and currents (EPSC) in FSI is minimal compared to that of pyramidal cells (Rotaru et. al, 2011), calling into question the role that NMDA receptors play in FSI physiology within the adult cortex. Interestingly, cortical FSI show a significant tonic NMDA current in vitro (Povysheva and Johnson, 2012), suggesting that while synaptic events onto FSI might not have a substantial NMDA component, glutamate could modulate FSI activity via extrasynaptic NMDA receptors. We tested whether FSI express functional NMDA receptors in the adult rat medial prefrontal cortex (mPFC) using whole-cell recordings to measure changes in excitability in response to bath application of NMDA and found that NMDA leads to an increase in FSI excitability which is accompanied by a slight depolarization. These responses were not due to activation of other cell types and glutamate release, as AMPA receptors were blocked by CNQX throughout each recording. Given that astrocytic glutamate transporters typically keep glutamate well confined to the synaptic cleft, we tested for the presence of extrasynaptic NMDA receptors by recording evoked synaptic responses in FSI in the presence and absence of the glutamate reuptake inhibitor DL-threo-β-Benzyloxyaspartic acid (TBOA). We found that synaptic responses acquired a prolonged NMDA component during TBOA application suggesting the presence of extrasynaptic NMDA receptors. Our results indicate that even in the absence of a significant synaptic NMDA component, extrasynaptic NDMA receptor activation is likely to play a meaningful role in regulating the activity of fast-spiking interneurons.

Title: Probing nmda receptor activation dynamics by combined patch-clamp single-molecule imaging microscopy

Authors: *H. LU, D. K. SASMAL;
Dept. of Chem., Bowling Green State Univ., Bowling Green, OH

Abstract: We have studied the NMDA receptor dynamics in Cho cells and neuron cells, using our newly developed combining real-time single-molecule fluorescence imaging with real-time single-channel electric current recording. We were able to probe cell electrophysiological responses and signals under ligand binding and membrane depolarization, and obtain an understanding the dynamics and mechanism of NMDA receptors at the molecular level. The kinetic behavior of ion channel proteins is regulated by subtle conformational changes that are often difficult to characterize by conventional ensemble-averaged static structure analysis and by interpretations of ion-channel electrophysiological measurements. We have analyzed and identified that subtle structural dynamics of ion channels play an important role in regulating channel function and selectivity, especially sensitive to the protein-lipid interactions and the peptide domain solvation dynamics. Using our unique approaches, we have obtained an understanding of how NMDA ion-channel activities are regulated by the conformational change and protein-membrane interaction dynamics. A new NMDA activation model has been postulated based on our experimental results.

Title: Tranexamic acid inhibits N-methyl-D-aspartate receptors in the hippocampus

Authors: *I. LECKER[1], D.-S. WANG[2], D. MAZER[4,3,2], B. A. ORSER[5,3,2];
[2]Physiol., [3]Anesthesia, [1]Univ. of Toronto, Toronto, ON, Canada; [4]Anesthesia, St. Michael's

Hospital, Keenan Res. Ctr. in the Li Ka Shing Knowledge Inst., Toronto, ON, Canada; [5]Anesthesia, Sunnybrook Hlth. Sci. Ctr., Toronto, ON, Canada

Abstract: Background: Tranexamic acid (TXA) is an antifibrinolytic drug widely used to prevent excessive blood loss during surgery. We have previously shown that TXA is a competitive antagonist of glycine receptors. Glycine is a co-agonist of N-methyl-D-aspartate receptors (NMDARs). Therefore, we hypothesized that TXA can inhibit NMDARs by interacting with the glycine binding site
Methods: Experiments were approved by the local ethics review committee. Electrophysiological data was collected from primary cultures of hippocampal neurons prepared from Swiss White embryonic mice. Whole-cell voltage clamp techniques were used to record NMDA-evoked currents in the absence and presence of TXA. Low concentrations of glycine (0.3 - 3 μM) were added to the extracellular solution. All data are expressed as mean ± SEM.
Results: TXA inhibited NMDARs in a dose-dependent manner. The threshold and concentration half maximal inhibitory concentration were 3 mM and 35.5 ± 4.1 mM, respectively. We also found that increasing the extracellular glycine concentrations enhanced the percentage of NMDAR blockade by TXA. The percent inhibition of NMDARs by TXA in the presence of low (0.3 μM) and high (3 μM) concentrations was 21.4 ± 4.9 % and 38.8 ± 5.7 %, respectively.
Conclusion: This is the first evidence showing that TXA inhibits NMDARs potentially by acting as a non-competitive antagonist.

Title: Time-of-day dependent changes in NMDAR subunits and effects on synaptic plasticity at intrathalamic connections

Authors: *S. ASTORI, A. LUTHI;
DNF, Univ. of Lausanne, Lausanne, Switzerland

Abstract: The subunit composition of synaptic NMDA receptors (NMDARs) remains modifiable throughout adulthood in response to sensory experience and learning. GluN2 subunits

are also modulated by arousal and sleep-promoting agents in different brain areas, and in particular GluN2A-NMDARs at hippocampal synapses are augmented by mild sleep deprivation and render synaptic plasticity susceptible to sleep loss (Longordo et al., 2009). NMDARs are also expressed within thalamic circuits that participate in thalamocortical rhythms apparent in the sleep electroencephalogram, but NMDAR function at intrathalamic synapses remains poorly understood. Here, we examined NMDAR-mediated transmission in the intrathalamic network and tested the GluN2-subunit content and its contribution to synaptic plasticity.
We studied glutamatergic synapses formed by thalamocortical axons on neurons of the nucleus Reticularis thalami (nRt) by means of patch-clamp electrophysiology in acute slices from 3-week-old mice sacrificed at different times of day. Mice were previously entrained to a 12h-12h light-dark cycle with lights on at 7 AM. The pharmacological profile of evoked NMDAR currents indicated an accumulation of GluN2A-NMDARs at the end of the dark phase, i.e. after the active period of the mice. In slices prepared during the last hour before light onset (6-7 AM), NMDAR currents were almost two-fold more sensitive to the GluN2A-preferring blocker NVP-AAM077 (50nM; 38.7±4.3% reduction, n=7) as compared to the first half (23.4±4.1%, n=8, $p<0.05$) and to the second half (21.1±1.8%, n=6, $p<0.01$) of the light phase. NMDA/AMPA ratios were comparable at the three time points (6-7 AM: 0.27±0.04; 11-12 AM: 0.29±0.05; 6-7 PM: 0.30±0.04).
We previously showed that NMDARs promote synaptic plasticity at thalamo-nRt synapses (Astori and Lüthi, 2013). In slices prepared during light phase (11-12 AM), the pairing of synaptic stimulation with repetitive low-threshold nRt bursting at frequencies typical for slow-wave sleep (1Hz) elicited long-term potentiation (44.8±9.9%, n=14, $p<0.01$). Synaptic changes were prevented by the GluN2B-antagonist CP101,606 (10µM; -0.7±2.9%, n=9, $p>0.05$). This finding was consistent with a major contribution of GluN2B to synaptic NMDAR currents during the resting phase (11-12 AM: 65.9±3.6% reduction with CP101,606, n=8, $p<0.05$), while GluN2A-NMDARs appeared to play a minor role. Our data suggest that GluN2B-NMDARs are dominating intrathalamic plasticity, with a time-of-day-dependent additional contribution of GluN2A-NMDARs that remains to be further defined.

Abstract: NMDA receptor antagonists, particularly these targeting the NR2B subunit are of therapeutic interest for the treatment of severe mood disorders. The receptor occupancy profiles of several NMDA receptor antagonists (30 mg/kg, s.c.) were compared in mouse hippocampus by *ex vivo* autoradiography using [^{3}H]MK-801, a non-selective channel blocker and [^{3}H]ifenprodil a selective NR2B antagonist. Subcutaneous administration of ketamine and memantine (inhibited [^{3}H]MK-801 but not [^{3}H]ifenprodil binding in mouse hippocampus. Ketamine reached maximal occupancy of [^{3}H]MK-801 binding sites after 15 min and rapidly cleared from the brain with no significant level of occupancy measured at the 1 h time point. Memantine significantly occupied [^{3}H]MK-801 binding sites throughout the 6 h time course. The selective NR2B antagonist CP101, and Ro 25-6981 inhibited [^{3}H]ifenprodil but not [^{3}H]MK-801 binding and significant levels of occupancy (above 50%) were measured throughout the 6 h time course. These data highlight the unique quick pulse target engagement profile of ketamine compared to other NMDA receptor antagonists.

Title: Amyloid-beta and agonist induce ion-flow independent conformational changes in the cytoplasmic domain of nmda receptors as monitored by fret-flim

Authors: *K. B. DORE, J. AOW, R. MALINOW;
Neurosciences, UCSD, La Jolla, CA

Abstract: Transmembrane receptors are well known to transduce extracellular ligand binding to intracellular signaling by transmitting transmembrane conformational changes. Whether ion-

channels perform the same task is not well established. Here we show that both ligand binding to the NMDA receptor and amyloid-beta application can drive a conformational change in the cytoplasmic domain of the NMDA receptor. We used GluN1 subunits tagged at the c-terminus with either GFP or mCherry as a sensor to measure these conformational changes with FRET-FLIM. Amyloid-beta produced an increase in FRET between the GluN1 c-tails that was dependent on the EphB2 receptor. However application of the specific agonist NMDA produced a reduction in FRET, meaning that the c-tails were driven farther apart upon direct agonist binding. Interestingly, both processes required ligand binding to the GluN2 subunit, and occurred despite blockade of NMDA receptor ion passage or of glycine binding to GluN1.

Title: NADA activates CB1 and TRPV1 independently to discretely regulate separate glutamate vesicle pools in the solitary tract nucleus

Authors: *J. A. FAWLEY, M. E. HOFMANN, M. C. ANDRESEN;
Dept Physiol & Pharmacol, Oregon Hlth. & Sci. Univ., PORTLAND, OR

Abstract: Endogenous lipid signals activate both the G protein-coupled cannabinoid receptor 1 (CB1) and the non-selective cation channel Transient Receptor Potential Vanilloid Type 1 receptor (TRPV1). This presents the possibility for activation of CB1 and TRPV1 by a single neuromodulator and for signaling crossover within the terminals of solitary tract (ST) afferents that express both receptors. ST afferents are differentiated by the presence of TRPV1 at C-fibers or its absence at A-fibers. While both afferent types have similar ready-releasable vesicle pools that generate synchronous glutamate release, only TRPV1+ afferents have an additional, TRPV1-operated vesicle pool that that releases both asynchronous and temperature-evoked glutamate. Here we tested whether NADA (5-10 μM), an endogenous lipid agonist with a high affinity for CB1 and TRPV1, can modulate the different forms of vesicular glutamate release from ST afferents. Shocks to the ST evoked synchronous glutamatergic EPSCs (ST-eEPSCs) with a jitter (SD of the latency) < 200 μs. Asynchronous release after ST-eEPSCs, or the lack thereof, identified TRPV1+ or TRPV1- synapses, respectively. Basal sEPSCs were measured prior to ST-eEPSCs. Repeated bath temperature ramps from 32-36° C reversibly increased the

rate of TRPV1-operated sEPSCs. NADA depressed ST-eEPSC amplitudes equally from CB1+/TRPV1+ and CB1+/TRPV1- afferents (66 and 67% ctrl, respectively) indicating comparable action at the readily releasable pool. Despite substantial reduction of ST-eEPSCs, NADA did not change the rate of basal sEPSCs from CB1+/TRPV1- afferents (99% ctrl) but enhanced both basal (140%) and temperature-evoked sEPSCs (135%) from TRPV1+ afferents with CB1. Interestingly, in TRPV1+ afferents lacking CB1, NADA only enhanced TRPV1-operated glutamate release, indicating that there is an additional, potentiating action at the TRPV1-operated pool. Therefore despite co-localization in most ST afferents, activation of CB1 had no effect on TRPV1 function and vice versa. Together, these data demonstrate that CB1 and TRPV1 discretely alter the different, independently regulated vesicle pools from ST afferents.

Title: TRPV1 antagonists block capsaicin but not temperature activation of TRPV1 at 2nd order neurons in the nucleus of the solitary tract

Authors: *M. HOFMANN, J. A. FAWLEY, M. C. ANDRESEN;
OHSU, Portland, OR

Abstract: In the nucleus of the solitary tract (NTS), most 2nd order neurons receive primary sensory cranial afferents that express the transient receptor potential vanilloid type I (TRPV1) receptor. Low pH (<5), high temperature (>43°C), or ligands activate TRPV1, which results in the influx of calcium through its non-selective cation pore. This increase in intraterminal calcium releases glutamate to generate EPSCs. We previously demonstrated that physiological temperatures (32-36 °C) activate TRPV1 to trigger increases in spontaneous EPSCs in the NTS. Here we investigated whether TRPV1 antagonists blocked temperature and capsaicin responses using patch recordings. In horizontal brain stem slices, solitary tract afferent stimulation recruited monosynaptic inputs and most cells responded to increased temperature and application of the TRPV1 agonist capsaicin with increased spontaneous EPSCs, i.e. they were TRPV1+. In

these cells, ramp increases in bath temperature from 32-36 °C over 3 minutes increased spontaneous EPSC rate but did not alter amplitudes. The TRPV1 antagonists A784168 and JNJ 17203212 attenuated responses to capsaicin but failed to inhibit temperature responses. In contrast, capsazepine and SB452533 significantly increased the temperature-induced increase in spontaneous EPSC rates but blocked responses to capsaicin. These results suggest that capsazepine and SB452533 may act as partial agonists at TRPV1 in the NTS. Capsaicin also blocks solitary tract evoked EPSCs and all four compounds were effective at preventing this action. These results demonstrate that each of these TRPV1 antagonists appear to effectively block the ligand activation site of TRPV1 but not the thermal activation site. The published profiles of several of these antagonists suggest that they effectively blocked multiple activation sites of TRPV1 (pH, heat, ligand) in heterologous screening systems. Our studies suggest that either central TRPV1 of cranial visceral afferents significantly varies from peripheral, often somatic afferent TRPV1 or solitary tract afferents are substantially sensitized to thermal inputs. For therapeutic use of TRPV1 antagonists, the presence of sensitive TRPV1 receptors coupled to neurotransmitter release in the NTS may present a potentially important focus for broad autonomic sequelae.

Title: Propofol restores TRPV1 sensitivity via a TRPA1-, NOS-dependent activation of PKCε in sensory neurons

Authors: P. SINHA ROY, B. PRUDNER, S. SINHA, *D. S. DAMRON;
Biol. Sci., Kent State Univ., Kent, OH

Abstract: Background: The intravenous anesthetic, propofol, restores the sensitivity of transient receptor potential vanilloid channel subtype-1 (TRPV1) receptors via a protein kinase C epsilon (PKCε)-dependent phosphorylation of the receptor. Moreover, propofol restores TRPV1 sensitivity via a transient receptor potential ankyrin channel subtype-1 (TRPA1)-dependent pathway. Our objectives were to determine the extent to which PKCε is involved in mediating the TRPA1-dependent restoration of TRPV1 sensitivity and the mechanism by which TRPA1

stimulation causes PKCε activation.
Methods: Lumbar mouse dorsal root ganglion (DRG) neurons were isolated and cultured for 24 hrs. F-11 cells were transfected with complimentary DNA (cDNA) for TRPV1 only or both TRPV1 and TRPA1. Intracellular Ca^{2+} concentration was measured in individual cells via fluorescence microscopy. Following TRPV1 de-sensitization with capsaicin (100 nM), cells were treated with various interventions prior to subsequent reapplication of capsaicin. Immuno-blot analysis of the total and phosphorylated forms of PKC and TRPV1 was also performed.
Results: In DRG neurons or F-11 cells containing both TRPV1 and TRPA1, PKCε inhibition (V1-2) prevented the propofol- and allylisothiocyanate (AITC) -induced restoration of TRPV1 sensitivity to agonist stimulation. In F-11 cells transfected with TRPV1 only, neither propofol nor AITC induced PKCε or TRPV1 phosphorylation. However, in F-11 cells transfected with both TRPV1 and TRPA1, both propofol and AITC increased phosphorylation of PKCε and TRPV1 that could be blocked with the PKCε inhibitor peptide, V1-2. Moreover, nitric oxide synthase inhibition blocked propofol-and AITC-induced restoration of TRPV1 sensitivity as well as PKCε phosphorylation, and V1-2 prevented the nitric oxide donor, SNAP, from restoring TRPV1 sensitivity.
Conclusion: These data indicate that the AITC- and propofol-induced restoration of TRPV1 sensitivity is mediated by a TRPA1-dependent, nitric oxide synthase-dependent activation of PKCε.

Title: The pharmacological action of eugenol involves rapid desensitization of TRPA1

Authors: *G. CHUNG, Y. KIM, S.-T. IM, I. JANG, S. OH;
Neurobio. & Oral Physiol., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: The structural similarity of eugenol to cinnamaldehyde, an active ligand for transient receptor potential ankyrin 1 (TRPA1), suggests that eugenol might produce its effect via TRPA1

in addition to TRPV1 as we reported previously. In this study, we investigated effect of eugenol on TRPA1 and TRPA1-associated orofacial pain. As the results, eugenol induced robust calcium responses and inward currents in a subset of rat trigeminal ganglion neurons that responded to a specific TRPA1 agonist, allyl isothiocyanate (AITC). The eugenol response was observed in trigeminal ganglion neurons from TRPV1 knockout mice and human embryonic kidney 293 cells that stably express TRPA1, which was inhibited by a TRPA1-specific antagonist HC-030031, but not by a TRPV1 specific antagonist capsazepine. Interestingly, we found that eugenol alleviated formalin-induced orofacial pain, which might be associated with rapid TRPA1 desensitization as revealed in electrophysiological experiments. In conclusion, our results demonstrate that fast desensitization of TRPA1 can account for novel molecular mechanism underlying pharmacological action of eugenol.

Title: Identification of functional microdomains within the S4-S5 linker of human TRPA1 channel

Authors: A. HYNKOVA[1], K. WITSCHAS[1], V. ZIMA[2], L. SURA[1], I. BARVIK[2], *V. VLACHOVA[1];
[1]Inst. of Physiol. AS CR, Prague, Czech Republic; [2]Inst. of Physics, Charles Univ., Prague, Czech Republic

Abstract: Transient receptor potential ankyrin 1 channel (TRPA1) is a sensory-neuron-specific ion channel that is gated in response to a variety of pungent chemicals, including allyl isothiocyanate and cinnamaldehyde, while it is strongly modulated by permeating Ca^{2+}. In the absence of any agonist, this channel can also be activated by depolarizing voltages. The molecular events transmitting such disparate signals to the central pore gate domain of the channel are unknown.
The molecular architecture of the transmembrane region of TRPA1 is thought to be potentially analogous to the large family of voltage-dependent potassium channels, in which the S4-S5 linkers, cytosolic loops connecting the S4 and S5 membrane spanning domains, mediate signal transduction and stabilize conformations associated with gating states. To address the functional role of the putative S4-S5 linker (Q851-F859) in TRPA1 channel, we performed mutagenesis studies targeting the highly conserved charged residues R852 and E854, and also E864 and K868 from the adjacent S5. Activation parameters including sensitivity to 100 µM cinnamaldehyde, the extents of Ca^{2+}-dependent potentiation and inactivation, and the steady-state voltage dependence of activation were explored for each mutant using whole-cell and single-channel recordings. The previously described gain-of-function mutation associated with familial episodic pain syndrome N855S (Kremeyer et al, 2010, Neuron 66: 671-680) was also examined for comparison. The effects of mutations at several residues had complex phenotypes indicating an unequal contribution of these residues to different modalities of TRPA1 activation and, therefore, apparently contradicting the predicted generic role of the S4-S5 linker in „simply“ coupling the S1-S4 module to the S5-S6 activation gate. Remarkably, the N855R mutation resulted in an increased sensitivity to cinnamaldehyde and a faster Ca^{2+}-induced inactivation kinetics without changing Ca^{2+} potentiation or steady-state voltage dependency. On the other hand, the charge reversal mutation R852E exhibited a gain-of-function when activated by cinnamaldehyde but impaired the potentiating effect of Ca^{2+}. Thus, the current work indicates that the S4-S5 linker acts as a signal integrator and a modality-selective transducer that is differentially involved in distinct sets of interactions that regulate the polymodal gating of the TRPA1 channel.

Title: Multiple ligand binding sites within intracellular N-terminus of TRPM1

Authors: *M. JIRKU[1], K. BOUSOVA[1], L. BUMBA[2], J. TEISINGER[1];
[1]Inst. of Physiol. ASCR, V.v.I., Prague, Czech Republic; [2]Inst. of Microbiology ASCR, v.v.i., Prague, Czech Republic

Abstract: Melastatin channel (MLSN) or TRPM1 (transient receptor potential melastatin 1) is the founding member of the subfamily of TRPM ion channels belonging to the superfamily of TRP channels. It is assumed that TRPM1 channel has six transmembrane domains with a pore domain between the fifth and the sixth segments. Intracellularly located N- and C-tails are responsible for regulation of TRP channels, which carry binding sites for signal molecules like calmodulin (CaM) or S100A1. [1-3]
TRPM1 is expressed in human melanocytes and bipolar cells in retina and participates in processes connected to vision. Mutations of TRPM1 gene are associated with congenital stationary night blindness in humans. [4-6] There is a scarcity of structural and functional properties of TRPM1 channel.
Two independent CaM /S100A1 binding sites on the intracellular N-terminus of rat TRPM1 were identified. Using bioinformatic approach we found Ca2+-dependent CaM /S100A1 binding sites in regions L242-E344 and A451-N566 corresponding to the consensus CaM binding motif 1-8-14. Several basic and hydrophobic amino acid residues responsible for binding in these regions of TRPM1 to CaM and S100A1 were determined.
Fusion proteins of both TRPM1 domains and appropriate mutants were expressed in E.coli and purified according to the two-step purification protocol. Amino acid sequence was checked by mass spectroscopy. The equilibrium dissociation constants for binding of CaM and S100A1 to TRPM1 fusion proteins and its mutants were estimated using by fluorescence anisotropy measurement and surface plasmon resonance measurement was employed as well. Experimental data also indicate that CaM and S100A1 bind to the same or overlapping binding sites.

Title: Involvement of TRPM2 channels in microglia activation

Authors: *H. JEONG[1], Y. KIM[1], S. JUNG[2], S. OH[1];
[1]Physiol. and Neurobio., Seoul Natl. Univ., SEOUL, Korea, Republic of; [2]Dept. of Pysiology, Hanyang Univ., Seoul, Korea, Republic of

Abstract: Microglia are resident macrophages in the central nervous system which become activated in response to peripheral tissue damage, inflammation, or nerve injury. Various endogenous immunomodulators are generated in the brain and spinal cord under pathological conditions. It has been demonstrated that microglia transform from ramified into ameboid morphology upon microglia activation which is associated with large amounts of Ca2+ influx in microglia. However, underlying mechanism of Ca2+ influx remains unknown. Transient receptor potential melastatin 2 (TRPM2) channel is a nonselective cation channel permeable to Ca2+ that is highly expressed in immune cells such as microglia. TRPM2 is activated by reactive oxidative species (ROS) including intracellular adenosine diphosphate ribose (ADPR), H2O2. Here, we examined the role of TRPM2 in microglia activation using BV-2 cells and murine primary cultured microglia.
Ca2+ imaging data showed that increase of [Ca2+]i in microglia was abolished in the presence of Gd3+, flufenamic acid, a TRPM2 channel blocker, and in Ca2+-free extracellular solution. TRPM2-mediated Ca2+ influx is occurred in wild-type microglia but not in TRPM2-/- microglia. LPS induced up-regulation of phospho-p38, a well known marker of microglia activation, in wild-type mice, which was abolished in TRPM2-/- mice. Furthermore, TRPM2 expression is increased following LPS treatment in wild-type microglia but not in TRPM2-/- mice. Our results suggest that TRPM2-mediated Ca2+ signaling leads to microglia activation.

Title: Kinetics of rapid covalent modification by electrophilic activators of TRPA1

Authors: *P. K. BAHIA, T. E. TAYLOR-CLARK;
Mol. Pharmacol. & Physiol., Univ. of South Florida, Tampa, FL

Abstract: Transient Receptor Potential Ankyrin 1 is a non-selective cation channel expressed largely on nociceptive sensory nerves. TRPA1 is activated by electrophilic compounds through covalent modification of select cysteine (Cys) residues on the intracellular N-terminus, and this mechanism is thought to contribute to nociceptor activation during oxidative stress. We analyzed the rate of electrophile-induced TRPA1 currents and calculated that TRPA1 is activated at rates > 1000 M-1s-1. Such rates are substantially faster than the electrophilic covalent modification of Cys on other proteins (<3 M-1s-1). We hypothesized that TRPA1 has unique properties that facilitate rapid electrophilic covalent modification of relevant Cys and thus are likely crucial for TRPA1 to act as a nociceptive transduction mechanism. We have expressed human TRPA1 with a C-terminal V5/poly-His tag in HEK293 cells. Using a pulse-chase experimental design with a fluorescently tagged electrophilic ligand (e.g. BODIPY-iodoacetamide, fluorescein isothiocyanate) we have studied the kinetics of TRPA1 covalent modification following immunoprecipitation. As expected human TRPA1 is rapidly bound by tagged electrophiles at rates >1000 M-1s-1. In comparison we found no significant binding of the ion channel Kv1.4. Surprisingly, the rattlesnake ortholog of TRPA1, which is functionally insensitive to electrophiles, reacted rapidly with electrophiles. In further studies we found that TRPA1 binding of electrophiles is not modified by intracellular polyphosphates (required for TRPA1 currents), and binding of BODIPY-iodoacetamide is irreversible over 40 minutes. By comparing functional TRPA1 responses with quantitative analysis of electrophilic binding, this study allows for novel insights into the activation mechanism of TRPA1.

Title: TRPV1 and TRPV2 are differentially involved in oral persistent pain associated with mucosal injury

Authors: *K. URATA[1], M. SHINODA[2], J. LEE[1], N. GIONHAKU[1], K. IWATA[2];
[1]Depertment of Complete Denture Prosthodontics, [2]Dept. of Physiol., Nihon Univesity Sch. of Dent., Tokyo, Japan

Abstract: The wearing of removable denture frequency causes mucosal injury. It is well known that mucosal injury causes severe persistent pain in the oral structures, which many patients suffer from. Previous studies have reported that transient receptor potential vanilloid (TRPV)1 is involved in oral persistent pain following mucosal injury. On the other hand, the involvement of TRPV2 in oral persistent pain remains unclear. It is important to know mechanisms underlying persistent oral pain associated with mucosal injury, to develop the appropriate prosthetic treatment for edentulous patients. In this study, we determined if TRPV1 or TRPV2 was involved in altered mechanical and heat sensitivity in the buccal mucosa (intra-oral tissue) or whisker pad skin (extra-oral tissue) following each tissue incision. Male Sprague-Dawley rats underwent a buccal mucosa or whisker pad skin incision (length: 10mm, Depth: 5mm), and the head-withdrawal reflex threshold (HWRT) to mechanical or heat stimulation of the buccal mucosa or whisker pad skin was analyzed. Moreover, the expression of TRPV1 and TRPV2 in trigeminal ganglion (TG) neurons innervating the buccal mucosa or whisker pad skin was examined, and the effect of local administration of TRPV1 or TRPV2 antagonist on mechanical or heat HWRT was tested. The HWRT to mechanical or heat stimulation of the buccal mucosa or whisker pad skin significantly decreased on day 3 after each incision. The number of TRPV1 and TRP2-immunoreactive (IR) TG neurons innervating the buccal mucosa or whisker pad skin significantly increased on day 3 after each tissue incision. The number of TRPV1 or TRPV2- IR TG neurons innervating the buccal mucosa was significantly larger than that of whisker pad skin. Local administration of TRPV2 antagonist caused significant increase in the HWRT to mechanical or heat simulation of buccal mucosa or whisker pad skin. On the other hand, TRPV1 antagonist administration induced significant increase in HWRT to heat but not mechanical stimulation of the buccal mucosa, and significant increase in HWRT to heat stimulation of buccal mucosa and whisker pad skin.

Title: PKD2L1 channels modulate medullar CSF-contacting neurons excitability by detecting changes in extracellular medium composition

Authors: A. ORTS-DEL'IMMAGINE, J. TROUSLARD, V. TILLEMENT, C. TARDIVEL, *N. WANAVERBECQ;
PPSN Lab. (EA 4674), Aix-Marseille Univ., Marseille, France

Abstract: In vertebrates, cerebrospinal fluid contacting neurons (CSF-cN) are present around the ventricular cavities and along the central canal (cc) where they have a peculiar morphology with a projection towards the cc that ends with a protrusion or 'bud' baring cilia. We have recently shown that CSF-cN are present in the dorsal vagal complex (DVC), a major hindbrain structure regulating autonomic functions. There, CSF-cN receive GABA- and Glycinergic synaptic entries and express functional polycystin kidney disease 2-like 1 (PKD2L1) channels. These channels are a subtype of the transient potential receptor (TRP) channels superfamily and their activity is modulated by variations in extracellular pH and osmolarity.
Using immunohistological techniques on adult PKD2L1:EGFP mice, we characterized the distribution and morphology of medullar CSF-cN. We also determined the consequences of PKD2L1 activation on CSF-cN physiology, using whole-cell patch-clamp recordings in brainstem slices obtained from adult wild type and PKD2L1-knock out (KO) mice.
We demonstrate that around the cc, PKD2L1+ CSF-cN are GABAergic with a density and distribution depending on their position along the rostro-caudal axis. These neurons project a dendrite towards the cc and posses a primary cilium on their soma, not on the bud. Further, they express PKD2L1 channels on the somatodendritic compartment but not on the axon.
In wild type mice, CSF-cN, recorded at a holding potential of -80 mV, exhibit a spontaneous unitary current with a low open probability. This activity is increased by extracellular alkalinization or hypo-osmotic shocks but inhibited by acidification. In current-clamp mode, CSF-cN action potentials discharge is enhanced by the increased PKD2L1 channel activity. In

contrast, in PKD2L1-KO litter mate, we did neither observe single channel activity nor a modulation of CSF-cN excitability.
Taken together our results characterize, for the first time, the morphology and phenotype of mice medullar CSF-cN and demonstrate that they express functional PKD2L1 channels. Further, PKD2L1 activity is modulated by changes in the extracellular medium. In turn, an enhanced activity of only few PKD2L1 channels participates in the modulation of CSF-cN excitability. Because CSF-cN are strategically positioned between CSF and parenchyma, they could detect circulating signals through PKD2L1 activation and convey the collected messages to cellular partners. Such a role might be particularly relevant at the level of the DVC a major regulatory site for autonomic functions and should be demonstrated by identifying and characterizing the neuronal network they are involved in.

Title: Irritants activate transient receptor potential channels and non-TRP channel receptors in trigeminal chemosensory neurons of mice

Authors: *R. LEHMANN[1], N. SCHOEBEL[1], H. HATT[2], C. VAN THRIEL[1];
[1]Leibniz Res. Ctr. For Working Envrn. and Human Factors, Dortmund, Germany;
[2]Cellphysiology, Ruhr Univ. Bochum, Bochum, Germany

Abstract: In many occupational fields employees are exposed to various harmful chemicals such as solvents and irritants. Trigeminal chemosensory nerve endings that innervate the facial skin, the tongue, and the mucosae of mouth and nose are the first sensors of the adverse effects of irritants. Such chemicals are detected by many different receptors and ion channels present in terminals of trigeminal sensory neurons, among them the important family of transient receptor potential (TRP) cation channels. Stimulation of multimodal trigeminal nerve fibers triggers reflexes like mucus secretion and respiratory depression. As an indicator of sensory irritation, the 50% decrease of respiratory rates (RD50) after inhalational chemical exposure of rodents is used as the most important bioassay (Alarie test). RD50 values have been established for a large number of chemicals, but so far the underlying cellular mechanisms of receptor activation and

signal transduction are unknown for most substances. In order to identify the cellular detection mechanisms of several chemically diverse irritants with known RD50 values, we employed calcium imaging and electrophysiological techniques in vitro. Using calcium imaging experiments, we observed robust and reproducible responses upon stimulation of trigeminal sensory neurons of mice with irritants like acetophenone (RD50 102.0 ppm), isophorone (RD50 27.8 ppm), or hexyl isocyanate (RD50 4.8 ppm). Based on dose-response relationships, we calculated EC50 values for the irritant-induced responses of isolated neurons. Interestingly, the EC50 values correlated with literature RD50 values indicating that tested irritants have similar effects in vitro and in vivo. Beyond the mere description of irritant effects on isolated trigeminal sensory neurons, we investigated the receptive mechanisms. By using specific blockers in calcium imaging experiments, we could show that some irritants activate TRP channels, whereas other irritants appeared to activate non-TRP receptors. These results were confirmed by electrophysiological recordings on heterologously expressed TRP channels. For the classification of chemicals with respect to their potency to elicit sensory irritation it is important to understand more about the underlying cellular mechanisms of receptor activation and signal transduction pathways and to identify differences between chemicals or classes of chemicals.

Title: TRPV4 is an important transducer that converts brain temperature energy into neuronal electrical excitability

Authors: *K. SHIBASAKI[1], M. TOMINAGA[2], Y. ISHIZAKI[1];
[1]Dept. of Mol. and Cell. Neurobio., Gunma Univ. Grad. Sch. of Med., Maebashi, Japan; [2]Natl. Inst. for Physiol., Okazaki, Japan

Abstract: Physiologicalbrain temperature is an important determinant of brain functions, and it iswell established that changes in brain temperature dynamically influence hippocampal neuronal activity. We previously revealed that the thermo-sensor TRPV4 (activated above 34°C) is activated by physiological brain temperature in hippocampal neurons and thereby controls their excitability *in vitro* (J. Neurosci. 2007, Shibasaki et al.). Here, we examined whether TRPV4 regulates neuronal excitability through its activation by brain temperature *in vivo*. We developed an original device to cool local brain temperature to inactivate TRPV4. The cooling treatment clearly demonstrated that constitutive TRPV4 activation was occurred in mouse brain, and we found that hippocampal theta-frequency electroencephalogram (EEG) activities in TRPV4KO mice during wake periods were significantly reduced compared with those in WT mice. Furthermore, slice patch clamp recordings from dentate gyrus of hippocampus revealed that WT neurons further depolarized compared with TRPV4KO neurons. Depending on the differences of the resting membrane potentials, WT neurons had smaller fEPSPs and higher firing than KO neurons at 35°C (above TRPV4 activation), however, the differences were abolished at 30°C (less than TRPV4 activation). Taken together, for the first time we reveal that TRPV4 is an important translator that converts brain temperature into neuronal excitability in mammals.

Title: Immunoelectron localization of the transient receptor potential vanilloid type 1 at inhibitory synapses in the mouse dentate gyrus

Authors: *P. GRANDES, M.-J. CANDUELA, J.-L. MENDIZABAL-ZUBIAGA, L. REGUERO, N. PUENTE;
Basque Country Univ., Leioa, Spain

Abstract: The transient receptor potential vanilloid type 1 (TRPV1) is a non-selective cation channel that acts primarily as pain sensor in the periphery but also modulates neurotransmitter release and synaptic plasticity in the brain. TRPV1 function must lay on its anatomical distribution in the peripheral and central nervous system regions where the channel has physiological roles. However, the anatomical localization of TRPV1 is well established in the periphery, but it is a matter of debate in the brain. We have recently shown that TRPV1 is highly concentrated in postsynaptic dendritic spines to asymmetric perforant path synapses in the outer 2/3 of the dentate molecular layer, being poorly expressed at the excitatory hilar mossy cell synapses in the inner 1/3 of the layer. On the other hand, the TRPV1 distribution at inhibitory synapses in the dentate molecular layer is still an open question.
In order to investigate this, we have used TRPV1 antibodies combined with a highly sensitive pre-embedding immunogold method for high resolution electron microscopy. TRPV1 immunoparticles were observed in dentate granule cell dendrites receiving symmetric synapses. The silver-intensified gold particles were mostly confined to postsynaptic membranes and were distributed at a relative short distance from the inhibitory synaptic contacts. Importantly, the TRPV1 distribution pattern at inhibitory synapses disappeared in the molecular layer of TRPV1-knockout mice. These findings give additional knowledge regarding to the fine TRPV1 localization obtained with high resolution electron microscopy in the rodent hippocampus.

Title: TRPV1 expression in central histaminergic neurons of rat and mouse

Authors: *R. DE LUCA, A. KERNDER, Y. YANOVSKY, O. A. SERGEEVA;
Inst. of Neuro and Sensory Physiology, Heinrich-Heine Univ. Duesseldorf, Heinrich-Heine Univ. Duesseldorf, Med. Faculty, Neurophysiol., Düsseldorf, Germany

Abstract: The vanilloid receptor 1 (TRPV1) is a nonselective cation channel activated by noxious heat, protons and capsaicin (Tominaga et al., 1998). Recently, it became evident that expression of TRPV1 is not restricted to the primary afferent nociceptors of the dorsal root, trigeminal and nodose ganglia, but also found in CNS (e.g. caudal hypothalamus) and in non-neuronal tissues (Cavanaugh et al., 2011). We have found recently that central histaminergic neurons controlling wakefulness express ASICs (acid-sensing ion channels) and respond to protons with excitation (Yanovsky et al., 2012). We report now that rat histaminergic neurons in the tuberomamillary nucleus (TMN) recorded in slices at 34°C increase firing rate under capsaicin (10µM) to 300±80% (n=4) of control. TRPV1 receptor antagonist capsazepin modifies inward currents in response to pH 6.0 in 30% of acutely isolated rat TMN neurons. With primers spanning fragment of C-terminus (nt 2045-2472, mouse TRPV1 cDNA sequence, NM_001001445), we detect by single-cell RT-PCR TRPV1 transcripts in 20% of rat and in 10% of mouse histaminergic neurons. With other primer sets we detect also the TRPV1 splice variants TRPV1B and Vr.5´sv (AF158248) in some rat neurons. We detect the mouse splice variant TRPV1β in the arcuate nucleus, but not in the TMN region. The majority of mouse histaminergic neurons respond to 10µM capsaicin with a decrease in firing (at 22°C) to 36±7% (12 out of 13 cells), whereas only 25% of the neurons respond to capsaicin 1µM. A subpopulation of cultured histaminergic neurons as well as neurons in slices from tomato-HDC mice show TRPV1 immunoreactivity. The expression of TRPV1 in TMN indicates a role of histaminergic neurons in the control of body temperature and in the systemic response to hypercapnia.

Title: The interactions of the intracellular regions of the TRPM4 channel with calcium binding proteins

Authors: *K. BOUSOVA[1], M. JIRKU[1], L. BUMBA[2], J. TEISINGER[1];
[1]Inst. of Physiology, Acad. of Sci. of the Czech Republic, Prague, Czech Republic; [2]Inst. of Microbiology, Acad. of Sci. of the Czech Republic, Prague, Czech Republic

Abstract: Transient receptor potential channel TRPM4 belongs to the TRP family of non-selective cation channels responsible for entry of mono and bivalent cations (K+, Na+, Ca2+, Mg2+) into the cell. TRP channels occur in membranes and participate on many processes e.g. sensitivity to warm and cold, taste, pressure, light and pain. [1, 2,] Especially the TRPM4 participates in processes ongoing in neurons, cardiomyocytes, pancreatic cells, etc. [1, 3, 4] Activity of the TRPM4 channel could be modulated by intracellular ligands, like calcium binding proteins calmodulin (CaM) and S100A1. [5]
There were characterized one CaM/S100A1 binding site in TRPM4 N-terminal region (NT) S583-A668, and another one independent CaM/S100A1 binding site in C-terminus domain (CT) V1050-S1114. The results from the previous experiments show that CaM and S100A1 compete for the same binding sites. [5] Fusion proteins of the corresponding lengths were expressed in E.coli and purified by HPLC. Sequences of the proteins were verified by Mass Spectrometry. To characterize CaM/S100A1 binding site on intracellular termini regions of the TRPM4 fluorescence anisotropy and surface plasmon resonance measurements were used. Several positively charged residues were identified to be responsible for binding of CaM and S100A1 within the TRPM4-CT S1050-A1114 and the TRPM4-NT S583-A668 domains. The binding of both domains to CaM and S100A1 respectively is Ca2+ dependent.

Title: Pharmacological characterization and modulation of a cation channel in *Aplysia* bag cell neurons

Authors: *R. M. STURGEON, N. S. MAGOSKI;
Dept. Biomed. and Mol. Sci., Queen's Univ., Kingston, ON, Canada

Abstract: Cation channels control excitability and are tightly regulated by a variety of modulators. A Ca^{2+}-dependent, voltage-gated, non-selective cation channel provides depolarizing drive to maintain the afterdischarge - a prolonged period of enhanced excitability in bag cell neurons required to initiate reproduction in *Aplysia californica*. Using single-channel recording, the Ca^{2+} activation of the cation channel and its response to modulators was investigated. Phosphatidylinositol-4,5-bisphosphate (PIP_2) breakdown is increased during the afterdischarge, yielding increased amounts of inositol triphosphate (IP_3) and diacylglycerol (DAG). We have previously reported that IP_3 dramatically right-shifts the Ca^{2+}-dependence of the cation channel (from EC_{50} 30μM to 20mM). We now find IP_3 competes with Ca^{2+} activation of the channel, reducing the P_o by 50% in the presence of high Ca^{2+}. Perfusing the same excised patch with high Ca^{2+} and no IP_3 did not reactivate the channel, suggesting IP_3 has sustained effects or binds tightly to the channel. Because PIP_2 and DAG modulate cation channels in general, the influence of these compounds on the *Aplysia* cation channel will be addressed, along with arachidonic acid, an important second messenger precursor. The *Aplysia* cation channel is transient receptor potential (TRP) channel-like. TRP channels play critical roles in a diverse group of physiological processes. Accordingly, the TRP channel inhibitors 9-phenanthrol (9PT), flufenamic acid (FFA), and SKF-96365 (SKF) all reduced the P_o of the cation channel in excised, inside-out patches. FFA, an inhibitor of many TRP channels, moderately reduced P_o by 45%, while 9PT, a specific inhibitor of TRPM4/5 channels, and SKF drastically decreased P_o by 90% and 80% respectively. In an effort to functionally compare the *Aplysia* cation channel to TRP channels, we have initiated cloning and expression of *Aplysia*-TRP-M and -C homologues in HEK293 cells. Characterizing the native *Aplysia* cation channel, and comparing its pharmacological properties with that of the *Aplysia*-TRP channels, will provide a molecular foothold towards determining the specific role for TRP channels in bag cell neurons. At present, we conclude that a TRP-like cation channel is tightly controlled by multiple modulators and its local lipid environment, providing a balance for initiating and maintaining the afterdischarge to regulate reproduction.

Title: An investigation into the binding site of M1 muscarinic acetylcholine receptor ligands

Authors: *A. J. MOGG, M. CRABTREE, L. M. BROAD;
Eli Lilly & Co. Ltd, Windlesham, United Kingdom

Abstract: Activation of the M1 muscarinic acetylcholine receptor (mAChR) is mediated either by binding at the orthosteric acetylcholine binding site or by interactions at allosteric sites on the M1 mAChR. Additionally some M1 ligands are reported to be bi-topic, with binding spanning both the orthosteric and allosteric sites.
The principle focus of this study was to investigate the binding mechanism of a range of muscarinic ligands including examples reported to be orthosteric (e.g. acetylcholine, Xanomeline, pilocarpine, oxotremorine-M) versus examples thought to be allosteric or bi-topic (e.g. BQCA, GSK-5).
The orthosteric radioligand ([^{3}H]N-methyl-scopolamine was used to compare the displacement profile of these ligands versus this prototypical orthosteric antagonist. Experiments were also conducted to assess if this profile of displacement was altered in the presence of BQCA, an M1 positive allosteric modulator. We also synthesised and characterised a novel [^{3}H]-radioligand thought to bind at an allosteric site on the M1 receptor to conduct further analysis of the binding of the ligands. In addition to competition binding assays with these radioligands, kinetic off-rates were also measured as an additional approach to deduce mechanism of binding.
The results confirm the allosteric mechanism of BQCA, but raise questions over the mechanism of binding of other agents previously reported to be either orthosteric or allosteric ligands. Additional studies will need to be conducted to help us confidently interpret these new findings.

Abstract: Alzheimer's disease is a severe and chronic mental illness for which only symptomatic treatment is currently available. Marketed drugs (eg Donepezil, Aricept®) enhance the cholinergic system by increasing the endogenous acetylcholine levels through inhibition of acetylcholinesterase. This results in a modest cognition-enhancing effect combined with side effects including nausea, diarrhea, salivation, vomiting and dizziness related to the non-selective activation of all subtypes of the muscarinic and nicotinic receptors. Preclinical evidence suggest that the M1 muscarinic receptor subtype plays an important role in cognition enhancement while activation of muscarinic M2 and M3 receptors are involved in the development of side effects. Selective activation of M1 by pursuing allosteric modulation, e.g. ectopic agonists or positive allosteric modulators (PAM) could boost the cognitive performance without the reported side effects. Recently however, it was reported that treatment with a selective M1 ectopic agonist did cause salivation and vomiting as side effects in a clinical study at low exposure levels in plasma. Therefore, a de-risking strategy was outlined to clarify whether selective positive allosteric modulation of M1 is a viable way forward for cognition enhancement in Alzheimer disease by characterizing a set of tool compounds with known diverse affinities to the different muscarinic receptors: an acetylcholinesterase inhibitor (Donepezil, Aricept®), ectopic agonists (GSK1034702, JNJ49791300) and M1 PAMs (BQCA, PQCA, JNJ54784964, Merck WO201184368).
M1 PAMs showed a specific M1 profile in a recombinant selectivity panel, consisting of the 5 human muscarinic receptors. Target engagement was demonstrated by IP1 increase both in primary rat hippocampal neurons and in rodent hippocampal brain extracts upon treatment with all compounds.
Ectopic agonists did not evoke the side effects that were reported in the clinic in rat in vivo models of proconvulsant activity, locomotor actvity, diarrhea, miosis, hypothermia and salivation. In contrast, in dog, ectopic agonists induced diarrhea, salivation and vomiting indicating that the dog is more sensitive than rodents for peripheral muscarinic-induced side effects. However, side effects induced by M1 PAMs were observed in rodents as well as in dogs at minimal exposures expected to be needed for target engagement. In conclusion, using in vitro and in vivo translational models, we enabled a data-driven decision to stop the further development of M1 PAMs.

Abstract: The muscarinic acetylcholine receptors (mAChR) are a family of class A G protein-coupled receptors comprised of five subtypes (M_{1-5}) expressed throughout the central nervous system (CNS). These receptors, together with their endogenous agonist, acetylcholine (ACh), play a vital role in regulating a wide range of physiological functions. Recent advances in the discovery of highly subtype-specific ligands for M_1 and M_4 have enabled researchers to pharmacologically elucidate the discrete functions of these subtypes in the CNS. However, discovery of M_5-selective ligands has remained challenging due to the highly conserved nature of the orthosteric site across the mAChR subtypes. Phenotypic studies of M_5-knockout mice have suggested that activation of M_5 may be therapeutically relevant for the treatment of chronic cerebrovascular diseases, acute ischemic stroke, and Alzheimer's disease. Furthermore, M_5's localization in dopaminergic neurons of the midbrain suggests that modulation of M_5 signaling may provide novel therapies for the treatment of Parkinson's disease and addictive behavior. Here we use parallel synthesis and in vitro molecular pharmacology techniques to identify,

optimize, and pharmacologically characterize highly selective M_5 positive allosteric modulators (PAMs) and negative allosteric modulators (NAMs) for use as probes to elucidate the role of M_5 in the CNS. We recently reported the discovery of the first submicromolar, highly-selective M_5 PAM, ML326 (VU0467903; hM_5 EC_{50} = 409 nM), but its poor physiochemical profile limited its utility as a pharmacological probe. At this point, a high throughput screen for M_5-specific ligands was performed on the MLPCN screening deck. Gratifyingly, this effort revealed a novel M_5 PAM scaffold along with a scaffold functioning as an M_5 antagonist. The PAM scaffold, VU0472882 (hM_5 EC_{50} = ~19 μM), was subjected to a multi-dimensional, iterative parallel synthesis effort in which multiple regions of the molecule were manipulated and juxtaposed to optimize the structure-activity relationships. This effort yielded an M_5-preferring PAM with a 100-fold improvement in potency, VU0481443 (hM_5 EC_{50} = 190 nM). The antagonist scaffold, VU0352221 (hM_5 IC_{50} = 3.5 μM) was similarly optimized, yielding VU0483253 (hM_5 IC_{50} = 300 nM). Further radioligand binding experiments have revealed VU0483253 to be acting allosterically; thus, VU0483253 represents the first submicromolar, highly M_5-selective NAM. Moreover, VU0483253 shows a favorable rat pharmacokinetic profile with low clearance (CL_p ~4.4 mL/min/kg), long half-life ($t_{1/2}$ ~16 hr), and good CNS distribution (brain-plasma K_p ~3.3).

Title: Characterization of Novel M4 PAM in Huntington's disease mouse model

Authors: *T. PANCANI, A. B. BOWMAN, T. J. BICHELL, T. M. BRIDGES, D. J. SCOTT, C. W. LINDSLEY, C. JONES, P. J. CONN, Z. XIANG;
Vanderbilt Ctr. for Neurosci. Drug Discovery, Vanderbilt Univ. Medcenter, Nashville, TN

Abstract:
Huntington disease (HD) is a neurodegenerative disease characterized by severe motor and behavioral alterations. The appearance of a hyperkinetic phenotype (chorea) marks the beginning of the motor symptomatic stage, is followed by akinesia and progressive conspicuous loss of striatal medium spiny neurons (MSNs). The causes responsible for this loss of striatal parenchyma are not understood; however, changes in signaling by glutamate and other neurotransmitters, largely precede the onset of the symptomatic stage of the disease, and might be responsible for behavioral alteration and striatal neuronal loss. Similar to humans, at an early age, HD mice show motor hyperactivity and stereotypic behavior, associated with increased striatal glutamate transmission, while late akinesia, is accompanied by striatal neuronal loss and decreased glutamatergic signaling. Data suggest that striatal cholinergic activity and function of muscarinic receptors (mAChRs) are compromised in HD, while clinical studies show that some cholinesterase inhibitors can provide significant symptomatic relief. M4 is one of the functionally predominant mAChR subtypes in the striatum. We now report that M4 activation inhibits evoked excitatory post-synaptic currents (eEPSCs), in MSNs by stimulation of cortico-striatal afferents in striatal slices. Furthermore, we found that eEPSC peak amplitude is increased in 50 days old YAC128 mice compared to WT, as shown previously. Accordingly, the amplitude of spontaneous EPSCs (sEPSCs) is increased in YAC128 mice. In these mice, an increase in glutamatergic transmission is accompanied by an increased M4-mediated inhibition of cortico-striatal eEPSCs, suggesting an increased M4 function at the cortico-striatal synapses and a decrease of striatal acetylcholine release previously described in HD. To investigate if pharmacological manipulation of M4-mAChRs would improve motor symptoms in early stage HD, we monitored the effects of a new M4 positive allosteric modulator, VU0467154, in open field, clasping and gait behavioral tests in 50 days old YAC128 mice. Our work supports the notion that M4 might represent a new therapeutic target for the treatment of HD.

Title: M5-muscarinic receptors engender different physiological outcomes in SNc neurons depending on their subcellular location

Authors: *D. J. FOSTER, P. R. GENTRY, Z. XIANG, C. W. LINDSLEY, P. J. CONN; Vanderbilt Ctr. For Neurosci. Drug Discovery, Nashville, TN

Abstract: Dysregulation of dopamine release from midbrain dopamine neurons is thought to underlie numerous disorders including Parkinson's disease and Attention Deficit Hyperactivity Disorder (ADHD). These midbrain neurons receive autonomous cholinergic afferents to their soma in the midbrain and to their terminals in the striatum. The only member of the muscarinic receptor (mAChR) family detectible in midbrain dopaminergic neurons is the M5 subtype. Here we use a combination of pharmacological and genetic tools to elucidate the role of this receptor in regulating substantia pars compacta (SNc) neuron physiology. At the SNc soma, the presence of functional M5 receptors was verified using an M5-selective positive allosteric modulator (VU0238429). In wild type animals addition of the non-selective mAChR agonist oxotremorine (Oxo-M) induced both inward currents and Ca2+ mobilization in these neurons. Concentrations of Oxo-M that produced submaximal currents / Ca2+ mobilization could be potentiated by inclusion of VU0238429. Furthermore, these responses were absent in M5 knock-out mice, suggesting that M5 is the only mAChR subtype mediating these effects. In wild type animals Oxo-M induced changes in firing rate as monitored using perforated patch recordings. Surprisingly, VU0238429 did not potentiate the increase in firing rate observed with sub-maximal Oxo-M concentrations, suggesting that M5 may play a more modulatory role at this subcellular localization. In the striatum, addition of Oxo-M induced an inhibition in dopamine release as monitored using cyclic voltammetry. Furthermore, VU0238429 potentiated the inhibition observed with submaximal Oxo-M doses suggesting that M5 activation in the striatum inhibits dopamine release. These results suggest that activation of the same receptor type in the same neuron can lead to very different physiological outcomes. While activation of somatic M5

leads to inward currents, activation of M5 in the neuron terminals induces an inhibition in neurotransmitter release.

Title: Selective activation of cholinergic interneurons induces long-lasting enhancement of intrinsic excitability of striatal medium spiny neurons

Authors: X. LV, C. LINDSLEY, P. J. CONN, *Z. XIANG;
Vanderbilt Univ., Nashville, TN

Abstract: The striatum is the primary gateway to the basal ganglia and critically involved in motor behaviors, habit formation and cognition, and its function is regulated by multiple neuromodulator systems including cholinergic systems. Cholinergic regulation of striatal function is mediated by acetylcholine (ACh) released from tonically active, giant aspiny cholinergic interneurons (ChIs) that have widespread and rich axonal arborizations within the striatum and acting on nicotinic and muscarinic receptors. Disturbance of striatal cholinergic system has been implicated in numerous neurologic and neuropsychiatric disorders including in Parkinson's disease, Huntington's disease, dystonia, Tourette syndrome and Schizophrenia. Of five muscarinic acetylcholine receptor (mAChR) subtypes, the M1 is one of the most abundant mAChR subtypes in the striatum. This receptor is highly expressed in both striatonigral and striatopallidal projection medium spiny neurons (MSNs). In previous studies, we and others have shown that cholinergic activation excites MSNs and this action is mediated by M1 receptors through modulating multiple potassium channels. In the present study, we used electrophysiology techniques in conjunction with optogenetic and pharmacological tools to determine the long-term effects of endogenous ACh release on MSN intrinsic excitability. The experiments were performed in acute striatal slices prepared from ChAT-ChR2(H134R)-EYFP transgenetic mice in which ChR2-EYFP was selectively expressed in ChIs. Whole cell current

clamp recordings were made from MSNs. An increase in endogenous ACh release was triggered by selective activation of ChIs that express ChR2 using blue laser light stimulation. We found that a brief increase in ACh release results in a long-lasting increase in excitability of MSNs, which is associated with hyperpolarization of action potential threshold and leads to increase in probability of EPSP-action potential coupling. In the presence of M1 selective antagonist VU0255035, the optical stimulation is no longer able to induce persistent increase in MSN excitability. This endogenous ACh induced and M1 receptor dependent long-lasting change in MSN excitability could have significant impact on striatal processing and might provide a novel mechanism underlying cholinergic regulation of the motor behavior and cognitive function.

Title: Effects of an anti-muscarinic component isolated from Micrurus lemniscatus venom on intracellular signaling by inositol phosphate and learning and memory of rats

Authors: *M. L. SANDOVAL, SR[1], T. S. SATAKE[1], M. O. CASOTTI[1], E. O. FRARE[1], T. J. OLIVEIRA[1], R. M. PORTO[1], I. F. C. BATISTA[1], F. M. ABDALLA[1], G. F. XAVIER[2]; [1]Lab. of Pharmacol., Butantan Inst., São Paulo, Brazil; [2]Lab. of neuroscience and behavior, Inst. of Biosciences/University of São Paulo, São Paulo, Brazil

Abstract: Elapid venoms usually exhibit muscarinic cholinergic components. The protein MTMlβ exhibits a N-terminal sequence determined by Edman degradation (NLYQFKNMIQCTNTRSCLDFADYGCYCGRGGSCT) and displays high similarity to proteins from Elapidae venoms already described, including a muscarinic inhibitor from *N. sputatrix*. This study investigated the effects of MTMlβ isolated from *M. lemniscatus* venom, on (1) the displacement of the hippocampal (Hpc) muscarinic antagonist [^{3}H]QNB, (2) the levels of

inositol tri-phosphate, and (3) performance of rats in the Morris' water maze. In experiments of saturation, Hpc membranes were incubated with [^{3}H]QNB (0,05-8,0 nM) both in the absence and presence of atropine (1 M) (30°C/1h). Scatchard analysis of specific binding yielded a dissociation constant (K_D)=0.88 ± 0,13 nM and binding capacity (B_{max}) = 1459.40 ± 235.26 fmol/mg of protein (n=5). Hpc membranes were also incubated with [^{3}H]QNB, both in the absence and presence of increasing concentrations of the MTMlβ and atropine (control) (30°C/1h). MTMlβ and atropine revealed one high affinity muscarinic binding site (respectively, pK_i = 7.38 0.15, n=4 and pK_i = 8.96 ± 0.08, n=4) to [^{3}H]QNB in the hippocampus. The MTMlβ (10^{-7} M) reduced the accumulation of intracellular [^{3}H] - inositol phosphates content in the rat hippocampus as induced by carbachol (10^{-5} M). Rats subjected to training in a working memory version of the Morris' water maze task, with the platform in a different location every day and 4 trials per day, received, on the 8th day, a Hpc injection (0.25µg/µL) of either MTMlβ or phosphate buffer (Controls) twenty minutes before training. Their performance did not differ significantly from that exhibited by the Control subjects. On the 9th day, however, when tested in the same task without any microinfusion, the subjects previously injected with MTMlβ exhibited significantly longer latencies and path lengths as compared to the Control subjects ($P < 0.0004$), and significant longer times spent within the day before critial quadrant ($P < 0.0083$). Interestingly, there were no significant main Trial and Trial x Group interaction effects ($P > 0.05$). These results indicate that the disruption of performance observed on the 9th day may be related to a better retrieval of the information about the platform location acquired on the previous day, during the MTMlβ effect. Hpc histology did not reveal any neuronal injury. In conclusion, the MTMlβ exhibits affinity for mAChRs and reduces the total inositol phosphates, revealing a profile of muscarinic antagonist in the rat hippocampus. The memory effects induced by MTMlβ intra-cerebral infusion deserve additional investigation.

Title: Early stress prevents the potentiation of muscarinic excitation by calcium release in adult prefrontal cortex

Authors: *E. PROULX[1], D. SURI[2], S. P. HEXIMER[1,3], V. A. VAIDYA[2], E. K. LAMBE[1,4]; [1]Physiol, Univ. Toronto, Toronto, ON, Canada; [2]Tata Inst. for Fundamental Res., Mumbai, India; [3]Heart and Stroke/Richard Lewar Ctr. of Excellence in Cardiovasc. Res., Toronto, ON, Canada; [4]Obstetrics and Gynaecology, Univ. of Toronto, Toronto, ON, Canada

Abstract: The experience of early stress contributes to the etiology of several psychiatric disorders and leads to lasting cognitive deficits, particularly in executive function. The modulation of the prefrontal cortex by muscarinic M1 acetylcholine (ACh) receptors is essential to these functions. These Gαq-protein coupled receptors trigger the release of calcium (Ca2+) ions from internal stores in addition to eliciting prolonged neuronal excitation. We used multiphoton Ca2+ imaging simultaneously with whole-cell electrophysiological recordings to demonstrate that ACh-induced Ca^{2+} release potentiates ACh-elicited excitatory currents in pyramidal neurons of prefrontal brain slice. The enhancement was sensitive to manipulations of intracellular Ca2+ as well as to interference with electrogenic Na+/Ca2+ exchange. This phenomenon was found to emerge in young adulthood, at a time when executive function typically reaches maturity. However, such developmental consolidation of muscarinic ACh signaling was abolished subsequent to the early stress of repeated maternal separation. Under these conditions, the adolescent phenotype was retained and developmental disruptions in the expression of multiple relevant genes were observed. Taken together, this work illustrates cellular mechanisms that may allow early stress to disrupt cognitive performance on tasks requiring mature executive function.

Title: Phosphorylation of GABAB receptors controls the activity of its auxiliary subunits

Authors: L. ADELFINGER, R. TURECEK, K. IVANKOVA, *M. GASSMANN, B. BETTLER;
Univ. of Basel, Basel, Switzerland

Abstract: GABAB receptors are the G-protein coupled receptors (GPCRs) for γ-aminobutyric acid (GABA), which is the main inhibitory neurotransmitter in the central nervous system. GABAB receptors are examples of GPCRs that are composed of principal and auxiliary subunits. The principal subunits have a typical seven-transmembrane domain topology and form fully functional heteromeric GABAB(1a,2) and GABAB(1b,2) receptors. These receptors bind the auxiliary K-channel tetramerization domain-containing proteins KCTD8, 12, 12b and 16 that influence receptor signaling (Schwenk et al., 2010, Nature 465:231-5). In particular, binding of the auxiliary subunit KCTD12 increases fast desensitization of receptor-mediated Kir3 currents. The mechanism underlying the desensitizing effect of KCTD12 on GABAB-mediated receptor responses are unknown. In principle, KCTD12 could influence the GABAB(1,2) core receptor, the G protein activation-deactivation cycle and/or the downstream Kir3 channel.
We now report that KCTD12-mediated desensitization of GABAB receptor responses is alleviated by protein kinase A activity. We have mapped a phosphorylation site in the receptor that mediates the effects of protein kinase A on KCTD12-mediated desensitization. We will provide an update on progress made in identifying the underlying mechanism.

Title: KCTD modulation of GABA(B) receptor function

Authors: M. Y. S. LI[1], C. J. MILLIGAN[1], H. WANG[2], *C. A. REID[1], S. C. HOPKINS[2], S. PETROU[1];
[1]Ion channel and disease group, Florey Neurosci. Inst., Melbourne, Australia; [2]Sunovion Pharmaceuticals Inc., Marlborough, MA

Abstract: Aim: KCTD12 and KCTD16 were identified as GABA(B) receptor auxiliary subunits, yet their functional significance has yet to be clearly elucidated. In order to better understand the functional role of these subunits, we characterized the in vitro impact of human KCTD12 and KCTD16 on GABA¬(B) receptor kinetics and pharmacology and characterized in vivo seizure susceptibilities using the KCTD12 knockout mice. Methods: For in vitro analysis we used a Xenopus laevis oocyte based automated two-electrode voltage clamp assay. GABA(B) receptor activated GIRK current was used to characterize the effects of the GABA(B) receptor agonist baclofen or the positive allosteric modulator CGP7930 on receptor kinetics in the absence and presence of KCTD subunits. In vivo studies compared the seizure susceptibility of the KCTD12 knockout mice with their wild type littermates to two seizure paradigms: thermogenic stress and PTZ induced seizures. For the thermogenic stress study, P14-16 mice were subjected to constant 42 Celsius degrees and the time to febrile seizure was recorded. For the PTZ induced seizure study, P40 mice were injected with PTZ (100mg/kg) and the latency to hind leg extension was measured. Results: Co-expression of KCTD12 with GABA(B) receptor accelerated the kinetics of response to agonist application (20-80% rise time from 2.8s to 1.3s) and the kinetics of subsequent receptor desensitization (increased from 3.9% to 54.7%, compared to GABA(B) receptor expression alone, n>7 oocytes). In contrast, KCTD16 co-expression did not significantly alter GABA(B) receptor kinetics. Analysis of baclofen dose-response curves showed that neither KCTD12 nor KCTD16 co-expression altered the EC50 or Hill slope (n>10 oocytes at each agonist concentration). However, the potentiating effect of CGP7930 on an EC20 concentration of GABA was enhanced in the presence of either KCTD12 or KCTD16 (from 11.5% to 20.3% and 24.4% respectively, n>33 oocytes). In the in vivo seizure studies, the sensitivity of thermogenic stress induced seizures was similar between KCTD knockout mice and wild type (n=7). However, a significant protection from PTZ induced seizure was observed in the KCTD12 knockout mice (survival rate from 33.3% to 81.8%, n=9-11). Conclusion: KCTD12 altered the kinetics of GABA(B) receptor, allosteric modulation and seizure susceptibility, presumably reflecting altered neuronal excitability. This raises the possibility of selective targeting of interactions between KCTDs and GABA(B) receptors.

Title: Enhanced postsynaptic $GABA_B$ receptor activity regulates excitatory neuronal architecture

Authors: *M. TERUNUMA[1], R. REVILLA-SANCHEZ[1], M. N. PANGALOS[2], S. J. MOSS[1,3]; [1]Dept Neurosci, Tufts Univ., BOSTON, MA; [2]Innovative Medicines, AstraZeneca, Alderley Park, United Kingdom; [3]Neuroscience, Physiol. and Pharmacol., Univ. Col. London, London, United Kingdom

Abstract: $GABA_B$ receptors are heterodimeric G protein coupled receptors composed of R1 and R2 subunits that mediate slow synaptic inhibition in the brain. Postsynaptic $GABA_B$ receptors which negatively regulate cAMP levels are predominantly found on dendritic spines adjacent to excitatory synapses and regulate neuronal activity. We have previously reported that $GABA_B$ receptors are intimately associated with protein phosphatase 2A and directly dephosphorylate S783 in the R2 subunit to enhance $GABA_B$ receptor endocytosis (Terunuma et al., PNAS, 2010). To examine the significance of postsynaptic $GABA_B$ receptors as a long-term determinant of neuronal activity, we have generated a $GABA_B$R2 subunit Serine to Alanine mutant knock-in mouse (S783A) to prevent S783 dephosphorylation. S783A mice expressed stable $GABA_B$ receptors on the plasma membrane and the basal PKA activity was significantly reduced. Reduced PKA activity led to decreased PKA-mediated phosphorylation of cAMP-response element binding-protein (CREB) and immediate early gene Arc/Arg3.1 expression, two proteins necessary for spatial memory consolidation. In addition, we found an elevated surface AMPA receptor expression and increased number of excitatory synapses, which paralleled with reduced Arc/Arg3.1 expression. Our study demonstrated a novel role of postsynaptic $GABA_B$ receptors regulating excitatory synaptic architecture.

Title: The effects of baclofen and phaclofen on performance in the Morris water maze

Authors: *C. F. HEANEY, M. M. BOLTON, A. S. MURTISHAW, J. W. KINNEY;
Dept. of Psychology, Univ. of Nevada, Las Vegas, Las Vegas, NV

Abstract: The primary inhibitory neurotransmitter, gamma-aminobutyric acid (GABA), has been implicated in regulating multiple neural processes including oscillations and long-term potentiation (LTP), as well as complex behavior such as learning and memory. Investigations have established that GABA is involved with neurons being entrained into oscillatory firing patterns, and these firing patterns have been shown to be beneficial for LTP and learning and memory. The metabotropic GABAB receptor has also been demonstrated to affect oscillations and LTP, however the role of this receptor in learning and memory tasks has not been as fully characterized as other GABA receptors. Limited data exist on the behavioral effects of altering GABAB receptor function in learning and memory tasks, and the results are varied. Utilizing male Sprague-Dawley rats, we tested the effects of the GABAB agonist, baclofen, and the GABAB antagonist, phaclofen, in the Morris water maze. Our results indicate that both ligands induced a change in learning and memory behavior in this task. We also analyzed hippocampal tissue for alterations to numerous protein markers and have found changes that may be related to the behavioral differences. These data indicate that alterations to GABAB receptor function may induce changes in learning and memory, and suggest a more prominent role for GABAB-mediated signaling in complex behavior.

Title: Natural substance neuroprotect against ethanol-induced neuronal apoptosis via $GABA_B$ receptors intracellular signaling in prenatal rat hippocampal neurons

Authors: *M.-O. KIM, S. ALI SHAH, I. ULLAH, T. KIM, G. YOON, H. LEE;
., Dept. of Biol., Gyeongsang Natl. Univ., GAZA 900, Jinju, Korea, Republic of

Abstract: Here we investigated the possible involvement of gamma-aminobutyric acid B1 receptor ($GABA_{B1}R$) in mediating the protective effects of black soybean anthocyanins against ethanol-induced apoptosis in prenatal hippocampal neurons because GABARs are known to play an important role in the development of central nervous system. Treatments were performed on primary cultures of prenatal rat hippocampal neurons transfected with or without $GABA_{B1}R$ small interfering RNA (siRNA). The results showed that when ethanol treatment was followed by anthocyanins treatment, cellular levels of pro-apoptotic proteins such as Bax, activated caspase-3 and cleaved poly (ADP-ribose) polymerase 1 (PARP-1) were decreased and the cellular level of the anti-apoptotic protein Bcl-2 was increased compared to treatment with ethanol alone. Furthermore, the effects of ethanol on cellular levels of $GABA_{B1}R$ and its downstream signaling molecules such as protein kinase A, calcium/calmodulin-dependent protein kinase II (CaMKII) and phosphorylated cAMP response element binding protein (p-CREB) were diminished or reversed by anthocyanins treatment. The ability of anthocyanins to reverse the effects of ethanol on cellular levels of Bax, Bcl-2, active caspase-3, cleaved PARP-1, $GABA_{B1}R$ and CaMKII were abrogated in cells transfected with $GABA_{B1}R$ siRNA. In a $GABA_{B1}R$-dependent manner, anthocyanins also inhibited the ability of ethanol to elevate intracellular free Ca^{2+} level and increase the proportion of cells with low mitochondrial membrane potential in the population. Cell apoptosis assay and morphological studies also confirmed the neuroprotective effect of anthocyanins against ethanol via $GABA_{B1}R$. Our data suggest that $GABA_{B1}R$ plays an important role in the neuroprotective effects of anthocyanins against ethanol (This work supported by NRF 2013-005232).

Title: GABA(B) receptors in the nucleus accumbens modulate dopamine release in a frequency dependent manner

Authors: *K. A. PITMAN[1], S. L. BORGLAND[2];
[1]UBC, Vancouver, BC, Canada; [2]Univ. of Calgary, Calgary, AB, Canada

Abstract: Behavioural studies have suggested that agonists of the γ-aminobutyric acid receptor type B (GABA(B)R) can decrease drug seeking. Consequently, GABA(B) agonists, such as R-baclofen, have been investigated for potential usage as anti-addictive compounds. Paradoxically, γ-hydroxybutyrate (GHB), a weak GABA(B) agonist, is abused recreationally. Ventral tegmental area (VTA) dopamine (DA) neurons and their projection to the nucleus accumbens (NAc) are part of a critical circuit mediating drug seeking behaviour. DA neurons fire at low frequencies but can fire in high frequency bursts and deliver higher terminal dopamine concentrations ([DA]) when animals are presented with reward-predicting stimuli. GABA(B)Rs are located in the NAc, however, it is unknown how activation of NAc GABA(B)Rs can modulate [DA]. Using fast scan cyclic voltammetry in brain slices containing the NAc core from adult male C57 Bl/6 mice, we found R-baclofen dose-dependently decreased DA release electrically evoked by a single pulse with an IC50 of 1.3 µM. The inhibition induced by R-baclofen (100 µM) was blocked by a GABA(B) antagonist (CGP52432, 1 µM). 10 mM GHB also decreased [DA]. Interestingly, R-baclofen-mediated or GHB-mediated inhibition of NAc [DA] was inversely proportional to stimulation frequency. Evoking dopamine (1 pulse or 5p 40 Hz stimulation) did not increase endogenous GABA effects at GABA(B)Rs in the NAc because CGP52432 alone had no effect on [DA]. Taken together, these data suggest that GABA(B) agonists acting at GABA(B)Rs in the NAc decrease [DA] in the NAc. The efficacy of inhibition of [DA] at burst-like frequencies by R-baclofen was greater than GHB suggesting a possible additional mechanism why, unlike GHB, R-baclofen may reduce craving.

Title: Patch-clamp analysis of anti-spasticity effect by baclofen in spinal ventral horn neurons

Authors: T. ABE[1], *T. NAKATSUKA[2], W. TANIGUCHI[2], N. MINE[1], N. TAKIGUCHI[1], N. MIYAZAKI[1], M. YAMANAKA[1], M. YOSHIDA[1];

Abstract: Gamma-aminobutyric acid (GABA) is one of the important inhibitory neurotransmitters in the central nervous system. GABA acts on GABA receptors classified into metabotropic G-protein-coupled $GABA_B$ receptor and ionotropic $GABA_A$ receptor. Severe spasticity caused by multiple sclerosis and spinal cord trauma cannot be adequately treated with oral antispastic medications. For the patients suffering from such spasticity, Baclofen, a $GABA_B$ receptor agonist is administered spinally via an implanted drug delivery device to treat spasticity and very effective. In order to determine the cellular mechanisms of $GABA_B$ receptor-mediated modulation of spinal transmission, we examined actions of baclofen on excitatory synaptic transmission in the ventral horn neurons using whole-cell patch-clamp recordings from spinal cord slices. In voltage-clamp mode (V_H = -70mV), the application of baclofen induced an outward current. Baclofen-induced outward current was observed in the presence of TTX or a non-NMDA receptor antagonist, CNQX. The baclofen-induced outward current was blocked by the addition of Cs^+ (K^+ channel blocker) or GDP-β-S (G protein activation inhibitor) in the pipette solution. The baclofen-induced outward current was mimicked by a $GABA_B$ receptor antagonist, CGP35348. These results indicate that baclofen mainly acts on postsynaptic motor neurons to induce an outward current via G-protein-mediated activation of K^+ channels through $GABA_B$ receptors. This may be a possible mechanism for anti-spasticity effect.

Title: ADX71441 treatment in a rat model for Charcot-Marie-Tooth disease type 1A downregulates the Pmp22 gene overexpression and reduces number of hypomyelinated axons

Authors: *M. W. SEREDA[1], M. RUDOLPH[2], R. FLEDRICH[2], R. STASSART[2], S. M. POLI[3], H. HADDOUK[4], T. PRUKOP[2];
[2]Dept. of Neurogenetics, [1]Max-Planck Inst. Exp. Med., Goettingen, Germany; [3]Translational Sci., [4]Toxicology, Addex Therapeut., Plan Les Ouates, Switzerland

Abstract: Charcot-Marie-Tooth disease is the most common inherited neuropathy and a duplication of the peripheral myelin protein 22 gene on Chromosome 17 causes the most frequent subform Charcot-Marie-Tooth 1A. Patients develop a slowly progressive dysmyelinating peripheral neuropathy and distally pronounced muscle atrophy. The amount of axonal loss determines disease severity (Fledrich et al., 2012). Pmp22 gene and protein expression is downregulated in-vitro in Schwann Cells by GABAB receptor activation mediated by Baclofen (Magnaghi et al. 2004; Melcangi et al. 2005). Furthermore, knock-out mice for GABAB receptor show an upregulation of Pmp22 gene expression and interestingly thinner myelin sheaths reflecting CMT-like pathology (Magnaghi et al. 2008).
OBJECTIVE: To test if the GabaB positive allosteric modulator ADX71441, lowers Pmp22 gene expression and ameliorates the phenotype in a Pmp22 transgenic rat model ("CMT rats") for Charcot-Marie-Tooth disease type 1A.
METHODS: Following two initial short term pilot studies (5days treatment) conditions were set for the following therapy. Long-term therapy study in CMT rats (n=14) and wildtype rats (n=12) consisted of treatment with ADX71441 at 6mg/kg s.c. every second day for 5 weeks, then 3mg/kg s.c. daily for 4 weeks or vehicle (sesame oil, 1 mL/kg). At the start of the treatment the CMT and the wildtype rats were 4 week old. At the end of the 9 week treatment, Pmp22 gene expression, grip strength, electrophysiology, and axonal counting were measured as well as ADX71441 drug level in serum.
RESULTS:
CMT rats showed overexpression of the Pmp22 gene, an axonal loss and reduced grip strength reflecting typical CMT1A features. 9 weeks ADX71441 therapy in CMT rats downregulated the 1.6-fold Pmp22 gene overexpression, reduced the number of hypomyelinated axons and increased compound muscle action potentials in peripheral nerves. ADX71441 therapy in wildtype rats did not affect physiological Pmp22 gene expression, axonal number and electrophysiological parameters. However, ADX71441 in wildtype rats caused a reduction in rat grip strength. Since there is not a comparable loss of grip strength between CMT treated and untreated, the data suggests some benefit by ADX71441 on underlying pathophysiology
CONCLUSION: ADX71441 could lower toxic PMP22 overexpression and potentially delay the progression of the disease and therefore offer a unique therapeutic opportunity for CMT1A patients

Title: Dynamic tuning of single neuron encoding through modulation of firing class and type of short-term plasticity

Authors: A. MOHAN[1], *C. STRICKER[2];
[1]Eccles Inst. of Neurosci., The Australian Natl. Univ., Canberra, Australia; [2]Dept. Neurosci, ANUMS / JCSMR, ANU, Canberra, Australia

Abstract: Synapses in neocortex show either release-dependent depression with a constant recovery rate (type 1) or release-independent depression with frequency-dependent recovery[1] (type 2). The firing characteristics can be classified as either class 1 (regular-firing) or class 2 (spike-frequency adapting)[2]. Based on a deterministic synapse model, we have shown that matching of type and class endows small networks with particular coding properties[3]. Here we focus on 2 aspects: Firstly, using electrophysiological recordings, we explore if firing class is under neuromodulatory control. Secondly, we study the encoding characteristics of all combinations between synapse type and firing class using a stochastic synapse model with one determining firing class.

Standard whole-cell recordings in layer IV of rat barrel cortex (14-18 d) were obtained. Firing was evoked by applying currents of 0.2 – 0.4 nA for 1.5 s every 30 s in the presence of either 10 µM noradrenaline (NA) or 20 µM 2-APB to block IP_3 receptors. Phase reset curves were measured using the direct method[4]. Bath-applied NA converted the firing with class 2 characteristics to that of class 1 (7 cells out of 9). In contrast, 2-APB converted class 1 firing to that of class 2 (6 cells out of 7). This suggests that NA can convert class 1 into class 2 firing and *vice versa* when IP_3 receptors are blocked.

Neurons were modeled with adaptive exponential Integrate-and-fire model and a previously developed stochastic model was used for the synapse. Stimulus typically consisted of 100 synapses relaying 1000 stimuli that were Gaussian-distributed in time. Timing of the first action potential was measured and averaged over 5000 trials. Based on reliability of the response and the standard deviation of the response time, we found that type 1 – class 2 acted as coincident while all other combinations as integrators.

Our results suggest that both pre- and postsynaptic dynamics shape single neuron encoding. Both dynamics are shaped by neuromodulators. We have previously shown that NA is preferential towards type 2 dynamics and now show that it also converts class 2 into 1 firing. This suggests that, for adrenergic modulation, both type 1-class 2 and class 2-type 1 configurations might be preferred configurations and that the dynamics are shifted *in tandem*, converting a coincidence detector into an integrator.

Title: Activation of extrasynaptic NMDARs at individual PF - MLI synapses in cerebellum

Authors: *B. NAHIR, C. E. JAHR;
Vollum Inst., OHSU, Portland, OR

Abstract: NMDA receptors (NMDARs) expressed by cerebellar molecular layer interneurons (MLIs) are not activated by single exocytotic events but can respond to glutamate spillover following coactivation of adjacent parallel fibers (PFs), indicating that NMDARs are perisynaptic. Several types of synaptic plasticity rely on these receptors but whether they are activated at isolated synapses is not known. Using a combination of electrophysiological and optical recording techniques in acute slices of rat cerebellum, along with modeling, we find that repetitive activation of single PF-MLI synapses can activate NMDARs in MLIs. High frequency stimulation, multivesicular release (MVR), or asynchronous release can each activate NMDARs. Frequency facilitation was found at all PF-MLI synapses but, while some showed robust MVR with increased release probability (Pr), most were limited to univesicular release (UVR). Together, these results reveal a functional diversity of PF synapses, which use different mechanisms to activate NMDARs.

Title: Selective synaptic inhibition accompanying dendritic spine activity

Authors: *N. TAKAHASHI[1], N. MATSUKI[2], Y. IKEGAYA[2];
[1]NeuroCure, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Grad. Sch. of Pharmaceut. Sci., Univ. of Tokyo, Tokyo, Japan

Abstract: Dynamic balance of synaptic excitation and inhibition (E/I) shapes the membrane fluctuations of cortical neurons and determines the patterns of neuronal outputs. Although recent studies revealed the E/I balance during spontaneous or evoked activities at cellular level, the E/I balance at the subcellular level, i.e., individual synapses, remains poorly understood. Combined large-scale spine imaging with somatic voltage-clamp recording, we simultaneously recorded synaptic excitation at individual spines over dendrites and inhibitory postsynaptic currents at the soma. We found that, at 22% of active spines, synaptic events were accompanied by transient somatic inhibition within 100 ms, whereas at the other spines, activity occurred without apparent somatic inhibition. Compared to synapses without inhibition, inhibition-coupled spines had larger spine heads and showed greater amplitudes in calcium transients by synaptic activation, potentially contributing to strong membrane excitation. Our results designates a dynamic modulation of somatic inhibition for synaptic excitation at individual spines, suggesting a novel E/I balancing mechanism that gates specific synaptic pathways.

Title: *In vivo* monosynaptic transmission between layer 2 GABA-ergic interneurons in mouse forepaw primary somatosensory cortex

Authors: *A. L. DORRN[1,2], J. F. A. POULET[1,2];
[1]Max-Delbrueck-Center For Mol. Med., Berlin, Germany; [2]NeuroCure - Neurosci. Res. Center, Charité-Universitaetsmedizin, Berlin, Germany

Abstract: In vivo measurements of monosynaptic transmission are necessary to characterize synaptic mechanisms underlying sensorimotor integration. Superficial layer cortical GABA-ergic interneurons form synaptic connections with both local excitatory and other GABA-ergic interneurons. Here we used double and triple two-photon targeted whole-cell recordings to measure GABA-ergic synaptic transmission between neighbouring layer 2 inhibitory interneurons in vivo in the urethane aneasthetised GAD67-GFP mouse forepaw primary somatosensory cortex. In a first step, we made spike-triggered averages from the spontaneous action potentials in putative pre- and postsynaptic neurons. This showed depolarizing peaks in nearby GABA-ergic interneurons during a spike suggesting strong common synaptic input to neighbouring interneurons thus making identification of monosynaptic connectivity between GABA-ergic interneurons using this method problematic. We therefore went on to trigger spikes with brief current injections across different brain states. This approach allowed us to investigate basic properties of inhibitory monosynaptic connections. It also revealed a strong impact of brain state on GABA-ergic synaptic transmission in vivo.

Title: Temporally and spatially distributed NMDA receptor-dependent synaptic input onto spinal ventral horn neuron dendrites during behavior

Authors: *M. H. ALPERT, S. ALFORD;
Biol. Sci., Univ. of Illinois, Chicago, CHICAGO, IL

Abstract: Vertebrate spinal ventral horn neurons possess elaborate dendritic arbors that transform both descending commands from the brainstem and those from local circuit activity into controlled movement. Glutamatergic and glycinergic synapses dispersed along dendrites actively shape neural output. However, little is known about how dendrites actively integrate spatially and temporally distinct synaptic inputs within intact neuronal networks during behavior. Thus, a fundamental question is: do physiological patterns of synaptic input reflect the output of individual neurons and how do these patterns impact behavior? To investigate this, we took advantage of the nearly intact, isolated lamprey CNS preparation. The brainstem locomotor control center can be stimulated to produce fictive swimming while the activity of individual neurons of the spinal ventral horn can be recorded using both imaging and electrophysiological modalities. During locomotion, spinal neurons receive phasic glutamatergic and glycinergic input, generating oscillations in membrane potential and intracellular Ca^{2+}. To examine both the electrical output of neurons and locations of NMDA-receptor dependent synaptic input, we combined sharp electrode electrophysiology with high-speed Ca^{2+} imaging. We demonstrate that spinal neurons show robust, phasic Ca^{2+} signals that are temporally and spatially variable throughout the dendritic tree. While these responses correspond to cellular activation and network swimming behavior, repetition of stereotypical activity either as patterns or as localized events fails to occur from cycle to cycle during locomotion. Discrete hotspots emerge, differing in both amplitude and temporal sequence, even amongst neighboring locations along a single dendrite. These signals exist subthreshold to spiking activity, but show enhancement during spikes, which can synchronize Ca^{2+} signals along and between dendritic branches. Ca^{2+} activity is abolished throughout the dendrites following local pressure-ejection of either the NMDA receptor antagonist, AP5, or the mGluR5 receptor antagonist, MPEP, while network activity persists. UV photo-uncaging of AP5 locally abolishes Ca^{2+} signals in discrete dendritic regions while sparing others. Thus, we conclude that dendrites of spinal ventral horn neurons receive locally distributed, NMDA receptor-dependent synaptic input during rhythmic network activity. This demonstrates that dendrites act as distributed computational devices in which the sum of dendritic input is powerfully transformed from a barrage of discrete and variable synaptic events into unified cellular output during behavior.

Title: Evidence of a functional gabaergic inhibition between reticular thalamic neurons revealed by an optogenetic approach in the mouse

Authors: *J. PAZ, J. R. HUGUENARD;
Neurol. and Neurolog. Science, Stanford, Stanford Univ., STANFORD, CA

Abstract: The reticular thalamic nucleus (nRT) is involved in perception, sensation, attention, consciousness and in generation of sleep spindle oscillations in thalamocotical networks. Inhibition between nRT neurons (i.e., intra-RT inhibition) is proposed to be critical for normal functioning of the thalamus by desynchronizing nRT neuron activity through a burst-shunting mechanism (Sohal and Huguenard, 2003) and a disruption of intra-nRT inhibition has been proposed to lead to abnormal thalamocortical oscillations underlying epileptic seizures. In contradiction with this theory, several studies showed a lack of a functional synaptic inhibition between nRT neurons in the mouse. Here we provide the first compelling evidence of a functional intra-nRT GABAergic inhibition in the mouse, and we demonstrate that a feed-forward intra-nRT inhibition can be recruited by excitatory afferents. we expressed the ChR2-H134R construct in C57/BL6J mice specifically in glutamatergic thalamocortical relay (TC) neurons projecting to nRT. This allowed us to selectively stimulate TC axons with 473 nm light in horizontal thalamic slices. As expected, optical activation of TC axons led to an early excitation enhancing the action potential firing of nRT neurons due to TC-nRT glutamatergic projections. Notably, in a third of recorded nRT neurons, the early excitation was followed by an inhibition and a reduced firing in nRT neurons. The optically evoked inhibition in nRT neurons was blocked by GABAa receptor antagonists suggesting that this evoked inhibition resulted from GABAa- receptor-mediated feed-forward inhibition in TC-nRT-nRT pathway. Furthermore, GABAa receptor blockers, besides preventing the inhibition, reinforced the early excitation at TC-nRT synapses. Indeed, an early excitation that usually consisted of 1-5 action potentials switched, in presence of picrotoxin, to a robust burst firing underlined by NMDA receptors. This result demonstrates that the nRT-nRT inhibition shunts TC-nRT excitatory synaptic inputs. This study demonstrates for the first time the existence of a robust functional intra-nRT hyperpolarizing and shunting inhibition in thalamic slices from the mouse. Current studies ongoing in our laboratory aim at determining whether cortical inputs can also recruit intra-nRT inhibition and which specific concomitant or independent activity patterns in TC and cortico-thalamic pathways most efficiently recruit intra-nRT feed-forward GABAergic inhibition.

Title: Oxytocin activation of fast-spiking interneurons enhances hippocampal spike transmission

Authors: *S. F. OWEN[1], S. N. TUNCDEMIR[2], G. FISHELL[2], R. W. TSIEN[2];
[1]Gladstone Inst. of Neurolog. Dis., San Francisco, CA; [2]NYU Neurosci. Inst., New York Univ., New York, NY

Abstract: Canonically, increasing inhibitory tone is expected to suppress neuronal responses to afferent stimuli. Here we show that the neuromodulator oxytocin selectively activates hippocampal fast-spiking interneurons. The resulting increase in inhibitory tone suppresses the spontaneous activity of CA1 pyramidal neurons, but surprisingly this is coupled with an enhancement of pyramidal cell responses to excitatory synaptic stimulation and a sharpening of evoked spike timing. The combination of a suppression of spontaneous activity paired with enhanced responses to evoked stimulation generates an improvement in network signal-to-noise, of possible importance to overall circuit performance. Activation of fast-spiking interneurons by the neuromodulator cholecystokinin or through the light-activated ion channel channelrhodopsin-2 yielded the same enhancement in evoked responses, confirming that this is a generally important network phenomenon. The selectivity of these interventions for fast-spiking interneurons sets them apart from other modulators, such as endocannabinoids, that target other interneuron classes in the hippocampus. The enhanced pyramidal cell spike throughput results from a suppression of disynaptic feed-forward inhibition that shifts the evoked excitatory-inhibitory balance. Paired whole cell recordings revealed that increasing fast-spiking interneuron activity induces a use-dependent depression at the fast-spiking cell to pyramidal cell synapse that

is necessary and sufficient to account for this reduction in feed-forward inhibition. On the other hand, excitatory transmission to pyramidal neurons and inhibitory neurons was directly assessed and appeared unaffected. These results delineate the action of oxytocin in the hippocampus, while also shedding light on a novel mechanism by which modulation of fast-spiking interneurons can modify hippocampal circuit activity.

Title: *In vivo* measurement of synaptic transmission between identified neurons in layer 2/3 mouse barrel cortex

Authors: *A. PALA, C. C. H. PETERSEN;
Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland

Abstract: In order to obtain a causal and mechanistic understanding of how sensory information is processed in the neocortex, it is essential to measure the properties of synaptic transmission between neurons in living animals. Here, we use a combination of single-cell optogenetics and whole-cell electrophysiological recordings to control and record the in vivo activity of individual pre- and post-synaptic neurons. Two-photon targeted single-cell electroporation (Kitamura et al. 2008) is used to deliver DNA encoding channelrhodopsin-2 (ChR2) to a single excitatory neuron located in upper layer 2/3 of the mouse barrel cortex. After allowing sufficient time for ChR2 expression, the excitatory neuron can be optically driven to fire repetitive, reliable and time-locked single action potentials. Parvalbumin-expressing (PV) GABAergic neurons (identified genetically in PV-Cre/Lox-Stop-Lox-tdTomato transgenic mice) or somatostatin-expressing (SST) GABAergic neurons (identified genetically in SST-Cre/Lox-Stop-Lox-tdTomato transgenic mice) located in the vicinity of the ChR2-expressing neuron are then sequentially

recorded in the whole-cell configuration while the ChR2-expressing neuron is optically stimulated to fire action potentials. Using this method, preliminary analyses suggest that: i) the synaptic connectivity rate from excitatory neurons appears to be higher to PV neurons compared to SST neurons; ii) the unitary excitatory postsynaptic potential (uEPSP) amplitudes on average appear to be larger in PV neurons than in SST neurons; and iii) the uEPSP rise-time and half-width appear to be longer in SST neurons compared to PV neurons. We are now investigating short-term synaptic plasticity of these two synapses as well as the impact of spontaneous network activity on synaptic transmission.

Title: Entorhinal-cortical HCN channel containing terminals originate from the forebrain

Authors: *M. M. SHAH, Z. HUANG;
Univ. Col. London, London, United Kingdom

Abstract: Hyperpolarization-activated Cation Non-selective (HCN) channels are highly expressed on hippocampal and cortical pyramidal cell dendrites. We have, though, recently demonstrated that HCN channels are also located on glutamatergic synaptic terminals that synapse onto medial entorhinal cortex (EC) layer III pyramids (1). Since afferents from cortical and non-cortical regions synapse onto EC layer III neurons, it is unknown which of these may contain presynaptic HCN channels. It is important to identify the neurons that contain these axonal channels as they inhibit glutamate release and are therefore important for regulating EC neuronal activity,
As a first step to address this question, we made entorhinal-cortical hippocampal slices from HCN1f/f,cre mice (in which HCN1 deletion is limited to the forebrain (2)) and their wild-type littermate controls. We recorded miniature excitatory synaptic currents (mEPSC) from EC layer III pyramidal neurons. We found that mEPSC frequency in HCN1f/f,cre mice was considerably enhanced compared to wildtype littermates. Further, consistent with our previous results using HCN1-/- mice in which HCN1 deletion was not restricted to the forebrain, bath application of the HCN channel inhibitor ZD7288 (15 μM) had little effect on HCN1f/f,cre mEPSC frequency.

Since HCN channels are expressed postsynaptically too and can alter EPSC shapes and summation, we performed FM1-43 imaging in slices using two-photon microscopy to directly measure synaptic release rates from individual terminals. Synaptic boutons in EC layer III were stably loaded with the fluorescent dye, FM1-43. Extracellular stimulation in the presence of the FM1-43 quenching, membrane impermeable dye, ADVASEP-7 was utilized to measure the rate of FM1-43 de-staining of terrminals (corresponding to exocytosis). We found that the rate and percentage of de-staining in HCN1f/f,cre slices was significantly greater than wildtypes. Additionally, whilst bath application of ZD7288 enhanced FM1-43 de-staining in wildtype slices, it had little effect in HCN1f/f,cre slices. These results suggest that the neurons containing pre-synaptic HCN channels are likely to be cortical in origin.

Abstract: The fundamental striatal dopamine (DA) is released following stimulation by two pathways: the classic nigrostriatal pathway and the cholinergic "hijack" pathway through a cholinergic transmission-induced dopaminergic transmission (CTDT). The timing of synaptic transmission is critical in striatal circuits, because ms-latency change can reverse a synapse from LTP to LTD under DA-dependent manner. Here, we determined temporal components of CTDT in striatal slices. Following a light stimulation at room temperature, an optogenetic cholinergic interneuron fired an action potential (AP) with a delay of 2.8 ms. The subsequent CTDT mediated by nicotinic ACh receptors had a total latency of 17.8 ms, comprising 7.0ms for cholinergic transmission, and 10.8 ms for the downstream DA terminal release. The AP-induced replenishments of the “apparent vesicle pool” in the complex CTDT synapse contained 1 s

absolute refractory period. CTDT provides an example of unraveling the building blocks during a fundamental synaptic terminal-terminal transmission.

Title: NMDA receptor-dependent dendritic calcium spikes underlie hippocampal complex bursts *In vivo*

Authors: *C. GRIENBERGER, X. CHEN, A. KONNERTH;
Inst. for Neurosci., Munich, Germany

Abstract: Complex spike (CS) bursts are an essential feature of hippocampal CA1 pyramidal cell activity in vivo. They were reliably observed in rodents, rabbits and cats (e.g. Kandel and Spencer, 1961; Fujita, 1975; Ranck, 1973). Their relevance for place cell activity in exploring animals was recently directly established in vivo (Epszstein et al. 2011). Burst firing is considered to be critically involved in the induction of long-term potentiation (Sjöström and Nelson, 2002). Under in vitro conditions spontaneous burst firing in CA1 pyramidal cells is

much less pronounced than in vivo and consists mostly of 2-3 spikes. There is evidence that these short bursts are of intrinsic origin and involve sodium (Azouz et al., 1996) and/or calcium conductances (Metz et al., 2005). However, it remained unclear how the longer lasting CS bursts in vivo (4-8 spikes) are generated. Here, we combined in vivo two-photon microscopy and targeted whole-cell recordings to study CS bursts in mouse hippocampal CA1 pyramidal cells in vivo. In order to perform dendrite imaging, the hippocampus was exposed by removing a small portion of the covering cortical tissue. Spontaneous CS bursts were detected in all neurons tested (36/36). They consisted of high frequency spikes (groups of 4-8 spikes or more at 100-300 Hz) riding on a depolarizing wave (mean amplitude 32±7 mV). We found that the frequency of spontaneous CS bursts increased when increasing the membrane potential. CS bursts were completely abolished in neurons that were dialyzed with the NMDA receptor (NMDA-R) antagonist MK-801, revealing an essential role of NMDA-R activation for CS bursts in vivo. They were associated with large dendritic calcium signals in all basal dendrites. These calcium signals persisted when intracellularly blocking sodium channels with QX-314. They were associated with depolarizing waves (mean amplitude 30±7 mV) that were highly similar to those recorded during CS bursts under control conditions. Interestingly, the intracellular application of a broad calcium channel antagonist (D-890, Kovalchuk et al., 2000) blocked the depolarizing wave-associated multibranch dendritic calcium signals, but not local dendritic hotspot calcium signals corresponding to synaptic inputs sites. Instead, blocking NMDA-Rs abolished both multibranch as well as hot spot calcium signals. Thus, our results identify a novel type of NMDA receptor-dependent dendritic calcium spike in the basal dendrites of CA1 pyramidal cells, which is essential for CS burst generation in vivo.

Title: *In vivo* monosynaptic excitatory transmission between layer 2 pyramidal neurons in mouse somatosensory cortex

Authors: *J.-S. JOUHANNEAU[1,2], A. L. DORRN[1,2], J. F. A. POULET[1,2];

Abstract: Local, excitatory synaptic connections between glutamatergic pyramidal neurons underlie neocortical sensory processing and cognition, yet there is very limited data available on identified monosynaptic cortico-cortical connections in vivo. To characterise basic properties of excitatory monosynaptic connections in vivo, we used 2-photon microscopy to make visually targeted recordings from 2-4 neighbouring (<100um) layer 2 pyramidal neurons in somatosensory cortex of urethane anaesthetised P18-P21 wild type mice. Connections were tested with brief current injections to trigger single action potentials. Excitatory neurons were selected based on their current evoked firing pattern, the in vivo 2-photon fluorescent image and post-hoc biocytin stain. In vivo, cortical neurons show spontaneous subthreshold membrane potential changes, defining different cortical states. During hyperpolarized Downstates it was possible to record small amplitude unitary EPSPs triggered by single presynaptic action potentials. We find that excitatory synaptic connections between layer 2 pyramidal neurons in vivo are sparse, most are small amplitude and have kinetics that resemble excitatory connections found in previous brain slice studies. During depolarized Upstates, the connection amplitude is reduced. Therefore we show state dependent modulation of monosynaptic glutamatergic transmission in vivo.

Title: Inhibitory synaptic transmission between Purkinje neurons and neurons of the cerebellar nuclei in mice with the Angelman syndrome-linked mutation GABRB3 m-/p+

Authors: A. A. TURNOWCHYK[1], *I. M. RAMAN[2];
[1]Interdepartmental Neurosci. Program, Northwestern Univ., Evanston, IL; [2]Northwestern Univ., EVANSTON, IL

Abstract: The autism-linked gene, *GABRB3*, codes for the β3 subunit of the GABAA receptor and the maternal copy of the *Gabrb3* gene is lost in Angelman syndrome. The β3 subunit of the $GABA_AR$ has been shown to directly alter channel kinetics and influence the localization of $GABA_A$ receptors, both of which are predicted to change the speed and efficacy of fast inhibitory synaptic transmission. Inhibitory transmission plays a central role in the cerebellum, because Purkinje (Pkj) cells, the principal projection neurons of the cerebellar cortex, are GABAergic. In addition, the cerebellum is consistently disrupted in autism spectrum disorders, and *Gabrb3* m-/p+ mice show deficits in cerebellar behaviors. We therefore investigated the effects of the m-/p+ mutation on synaptic transmission from Pkj cells to their target neurons in the cerebellar nuclei (CbN) in cerebellar slices from P17-24 mice. We made whole cell patch clamp recordings from large projection CbN cells and evoked trains of IPSCs by stimulating Pkj axons at 100 Hz for 500 ms at 36°-37.5°C with synaptic excitation blocked by DNQX and CPP. In both littermate control (m+/p+) and m-/p+ neurons, IPSCs decayed with a fast time constant of ~1-2 ms and a variable slow component. We measured both the peak IPSC relative to the preceding baseline (the 'phasic' IPSC), as an indicator of presynaptic release, and the IPSC remaining just before each stimulus (the 'tonic' IPSC), as an indicator of postsynaptic kinetics. In m+/p+ cells, phasic IPSCs depressed only mildly, with the 50^{th} response at 78±18% of the 1^{st} (N=9). Likewise, in m-/p+ mice, the phasic IPSC stayed at 71±6% of the 1^{st} peak (N=13). In m+/p+ cells, the IPSCs did not decay fully between stimuli, so that the tonic current increased over the first 5 IPSCs, reaching 14 ± 3% of the 1^{st} IPSC peak and remaining at 10-13%. In contrast, in m/p+ cells, the tonic current increased only to 6±2% by the 5^{th} stimulus, and stayed at 5-7%. Thus, the β3 subunit regulates the kinetics of fast GABAergic IPSCs at this synapse. Next, we tested whether m-/p+ cells might have an enhanced ability to follow rapid trains of synchronous IPSCs, since the tonic IPSC is the primary factor suppressing CbN cell firing, and our recent work suggests that synchrony of Pkj cells can reduce tonic current and permit CbN cells to fire well-timed spikes between IPSCs. Unlike m+/p+ cells, which did not entrain perfectly to 100 Hz trains, m/p+ cells generated at least one spike after every synchronous IPSC, even at 100 Hz. These data support the hypothesis that faster IPSC kinetics as a consequence of reduced β3 expression result in a higher firing frequency in CbN cells during synchronous Pkj cell input.

Title: Abnormal cytoplasmic calcium dynamics in central neurons of a dystonia mouse model

Authors: *S. IWABUCHI, J.-Y. KOH, N. C. HARATA;
Dept. of Mol. Physiol. & Biophysics, Univ. of Iowa, Iowa City, IA

Abstract: Increased activities of cytoplasmic calcium and the excitatory neurotransmitter glutamate have been independently implicated in the pathophysiology of dystonia characterized by sustained involuntary muscle contractions. However, cellular-level evidence linking these two features is not available. Here we show that glutamate-dependent changes in neuronal calcium dynamics occur in a knock-in mouse model of DYT1 dystonia, the most common hereditary form of this disorder. Fluorescence-based analysis of the dynamics of cytoplasmic calcium concentration ($[Ca^{2+}]_c$) in cultured hippocampal neurons shows that electrical stimulation depolarizes the neurons and increases the dendritic $[Ca^{2+}]_c$, which then decays slowly to the pre-stimulus level. Whereas the peak amplitude of $[Ca^{2+}]_c$ was not affected, the decay period was prolonged in hippocampal neurons of heterozygous mice whose genotype reflects the human condition. We found that this effect was blocked by the antagonists of ionotropic glutamate receptors, and confirmed that glutamate receptors are present in these neurons. In contrast, no $[Ca^{2+}]_c$ abnormality was found in cultured striatal neurons of heterozygous mice that were composed of GABArgic medium spiny neurons and GABArgic interneurons. These results suggest that glutamate-dependent abnormality represents an important cellular phenotype of dystonia.

Title: Electrical and chemical synapses drive fine-scale correlations in the retina

Authors: *A. J. MCLAUGHLIN[1], S. TRENHOLM[1], D. J. SCHWAB[2], G. B. AWATRAMANI[1];
[1]Univ. of Victoria, Victoria, BC, Canada; [2]Physics, Princeton Univ., Princeton, NJ

Abstract: Introduction
Throughout the CNS, neurons that are electrically coupled via gap junctions often exhibit fine-scale correlated activity (on a millisecond time scale). However, given the low conductance of gap junctions, it is unclear how they effectively drive correlated activity. Here we characterize the biophysical properties of electrical connections between superior coding directionally selective ganglion cells (DSGCs) in the retina and investigate how gap junctions cooperate with chemical synapses to promote synchronized activity.
Methods
Using 2-photon targeted whole-cell voltage-clamp techniques we recorded the physiological responses of DSGCs labeled in the Hb9 transgenic mouse retina.
Results
When DSGC subtypes coding all four cardinal directions were loaded individually with the gap junction permeable tracer Neurobiotin, only the Hb9::eGFP-labeled population exhibited homologous tracer coupling. Consistent with these anatomical findings, only superior coding DSGCs exhibited voltage-dependent feedback spikelets (when DSGCs were depolarized above 0 mV) that were sensitive to gap junction blockers. Recordings from pairs of neighboring Hb9+ DSGCs revealed that coupling was reciprocal, non- inactivating and relatively weak (<1 nS). Depolarization by direct current injections into individual DSGCs only led to subthreshold activity in neighboring cells, indicating that gap junction signals on their own cannot activate their neighbors. Nevertheless, when DSGCs were stimulated with stationary or moving spot stimuli (evoking mixed chemical and electrical synaptic activity), spike activity between neighboring cells exhibited robust correlations. Cross-correlograms computed from stimulus driven activity revealed sharp bimodal peaks at + 2ms with a trough centered around 0 ms. These were blocked by the gap junction antagonist 18-beta-glycyrrhetinic acid suggesting an obligatory role for reciprocal coupling. Fine-scale correlations were not present in pairs of other types of DSGCs with overlapping receptive fields but orthogonal directional preferences. Thus we conclude that both chemical and electrical synapses are required for generating correlated activity in the retina.
Conclusions
We identified a transgenic mouse line which labels a gap junction coupled population of superior

coding DS ganglion cells. This provides a novel tool for the study of electrical coupling between DSGCs. Our results indicate that electrical and chemical synapses cooperate to produce correlated activity between neighboring superior coding ON OFF DSGCs, which is expected to significantly impact information flow to higher centers.

Title: Development of network connectivity in human pluripotent stem cell derived neural networks

Authors: *M. E.-L. MÄKINEN, L. YLÄ-OUTINEN, D. FAYUK, S. NARKILAHTI;
IBT, Univ. of Tampere / Biomeditech, Tampere, Finland

Abstract: Neural cells integrate into existing networks using similar mechanisms as newborn neural cells during fetal development (Jäderstad et al., 2010, Stephens et al 2011). During embryogenesis, the developing brain expresses a form of spontaneous synchronous network activity (Voigt et al., 2001). Similar activity develops spontaneously in the networks formed by human pluripotent stem cell (hPSC) derived neurons in vitro (Heikkilä et al., 2009). However, the cellular composition and the intercellular connections in spontaneously active neural networks remain unclear. Here, we studied the cellular components of network communication underlying the formation of early activity in hPSC derived neuronal networks.
hPSCs were differentiated to neurons as described earlier (Lappalainen et al., 2010). The analysis of functional cellular subpopulations and connections requires activity measurements. The activity of neural cell cultures is commonly measured with microelectrode arrays (MEAs) or calcium imaging. These two methods were combined with pharmacological studies to follow the spontaneous network activity and to dissect the mechanisms mediating activity during the maturation of the networks.
The early network activity was found to be mediated by gap junctions as well as by glutamatergic and GABAergic signalling. The amount of gap junction and GABA mediated signaling seemed to change during network maturation. In addition, the dependency of the

network activity from these mechanisms was different between differently derived networks. Furthermore, networks were found to contain subnetworks responding differently to pharmacological treatments.
The activity in hPSC derived neuronal networks is mediated by mechanisms similar to those occurring during the early brain development. The described pharmacological protocols seemed promising for studying differences in cellular composition and functional connections. Thus, human pluripotent stem cell derived neuronal cell cultures are a suitable in vitro platform for studying the integration of neurons into functional tissue.

Title: Powerful control of principal cell output by parvalbumin and cholecystokinin/CB1 cannabinoid receptor expressing interneurons in mouse basolateral amygdala

Authors: *J. VERES, G. A. NAGY, V. K. VERECZKI, N. HÁJOS;
Inst. of Exptl. Medicine, Hungarian Acad. of Sci., Budapest, Hungary

Abstract: Synaptic inhibition powerfully controls the firing activity of principal cells (PCs) in the basolateral nucleus of the amygdala. However, it is currently unknown how the different inhibitory interneuron types contribute to the GABAA receptor-mediated synaptic transmission regulating the discharge of excitatory cells. In this work we tested the ability of interneurons expressing parvalbumin (PV-INs) or cholecystokinin and CB1 receptor (CCK/CB1-INs) to control the output properties of PCs in the basolateral amygdala.
We recorded from synaptically connected pairs of interneurons and PCs using in vitro whole-cell or perforated patch-clamp techniques. Amygdalar slices were prepared from PV-EGFP and CCK-DsRed transgenic mice. First, we recorded IPSCs and IPSPs in the postsynaptic PCs upon

evoking action potentials in the presynaptic interneurons and analyzed the basic kinetical properties of the synaptic transmission. Then we tested the ability of the interneurons to inhibit action potential generation in PCs evoked by somatically injected currents and to alter the timing of the output of their postsynaptic partner. We found that the majority of PV-INs and CCK/CB1-INs could veto PC firing and -depending on the timing of the inhibition- delayed the generation of the action potentials. When we discharged the PCs with electrically evoked EPSPs, we could observe a significant, but less robust inhibitory control of PC output by both cell types. During the recordings we labeled both the pre- and the postsynaptic cells for subsequent anatomical analysis and compared the physiological properties of the synapses with the corresponding anatomical features at the light and electron microscopic levels. We found that both types of interneurons contacted somatic and dendritic domains of PCs with similar distribution pattern, and that the location of the contacts correlated with various electrophysiological properties of the connections.
Although PV-INs and CCK/CB1-INs may play distinct roles in cortical network functions, these results suggest that under our circumstances both interneuron types can effectively control action potential generation in PCs. By regulating PC output these GABAergic cells are in the position to powerfully contribute to the formation and expression of fear memories in the basolateral amygdala.

Title: Optogenetic investigation of axo-axonic inhibitory synapses within a cortical circuit

Authors: *X. WANG, Q.-Q. SUN;
Zoology and physiology 3166, Univ. of Wyoming, University Of Wyoming, WY

Abstract: GABAergic synapses provide an inhibitory tone to local circuits, thereby determining their final output. Among diverse GABAergic interneurons, axo-axonic synapses (AAS) provided by chandelier cells play a key role in the regulation of neural oscillation and

epileptogenesis. Chandelier cells provide a powerful control over the neural output of principal neurons by innervating the axon initial segments (AIS). However, little is known about their functional properties, due to technical challenges. Our recent work revealed that the piriform cortex (PC) inhibitory circuits are extremely unique. Virtually every pyramidal neuron in the PC area is innervated by robust AAS. This feature makes the PC the brain area with the highest density of AAS. In animal studies for temporal lobe epilepsy, the PC is the most prone to seizures and highly active chronic epileptic genesis foci within the limbic system. The unique anatomical and physiological features of the AAS make it an important component of the endogenous anti-epileptic circuit. Optogenetic tools, providing precise control of neural activities in a space and time specific fashion, have become the tools of choice for the study of neural circuits. This combined with in vitro slice electrophysiology, can shed light on the function of AAS innervations in the inhibitory network of the PC of mice. This lab has developed a convenient fiber optic approach to achieve subcellular laser stimulation at the AIS. After that, we used gramicidin-based perforated patch recordings to study the functional effects of AAS. Lastly, we induced "epileptic-form" activities and examined the effects of selective activation of AAS. We concluded that AAS have very transient veto power to neuronal excitability. Thus, techniques to selectively activate AAS may be used in treating neurological disorders such as temporal lobe epilepsy.

Title: The hysteresis of evoked spike patterns in a cultured neuronal network depends on the strength of functional connections

Authors: *H. ITO, S. KUDOH;
Sch. of Sci. and Tech.,Kwansei Gakuin Univ., Sanda-City , Hyogo, Japan

Abstract: Cultured rat hippocampal neurons autonomously form a complex network on a multielectrodes array (MEA) dish, which is useful for analyzing network dynamics. Spontaneous activity starts to be observed from approximately 7 days in vitro (DIV). The structure of the network developed in order to form complex dynamics. We applied sequential electrical stimuli to the neuronal network. Shots of electrical stimuli were applied 4 times at a trial. Each of the first 2 stimuli, stim1 and stim2, were applied as a single stimulus with enough inter-stimulus interval. Last 2times, stim3 and stim4, were paired pulse stimulation with short ISI (stim4 with stim3 as pre-stimulation). The interval of stim3 and stim4 was set as 1 s, 2 s, 2.5 s, 5 s and 10 s. We found that electrical activity pattern by stim4 was affected by existence of stim3 in the case that interval between the stim3 and stim4 was within 2 s, in the case that the neuronal network was cultured for relatively long period (over 70 DIV). The hysteresis has not been observed in a network cultured for relatively short period (less 30 DIV). The origin of this difference is expected to be the differences in synaptic efficacy. To confirm the hypothesis, same experimental procedures were performed in the Mg2+-free Rec.Sol, which was expected to induce transient increase of synaptic efficacy by the activation of NMDARs and Ca2+channels. Under the raised synaptic efficacy, hysteresis was also observed in short period (aapproximately 30 DIV) cultures. Thus, synaptic efficacy controls the hysteresis of Network response. The hysteresis is generated depending on the internal state of the semi-artificial neuronal network on a MEA dish.

Title: Reuptake transporters limit dopamine but not noradrenaline pooling during autoreceptor feedback inhibition

Authors: N. A. COURTNEY, *C. FORD;
Physiol. and Biophysics, Case Western Reserve Univ., Cleveland, OH

Abstract: G-protein coupled receptors (GPCRs) are typically located extrasynaptically and activated by transmitter spillover. As such, slow synaptic potentials mediated by neurotransmitters acting via GPCRs classically signal through volume transmission. Whether

this holds true for all GPCRs remains unclear. Here, we compared metabotropic inhibitory post-synaptic currents (IPSCs) mediated by D2 dopaminergic receptors in the ventral tegmental area (VTA) with IPSCs mediated by alpha2 noradrenergic receptors in the locus coeruleus (LC). Both D2- and alpha2-receptors are GI coupled GPCRs that generate their IPSCs by causing the opening of G-protein coupled, inwardly rectifying potassium channels (GIRKs). Comparisons of D2- and alpha2-IPSCs evoked by a single extracellular stimulation revealed that alpha2-IPSCs were 250% slower to rise (10%-90% rise time), 400% longer in duration (half-width), and 625% more variable in decay time (standard deviation; alpha2-IPSC: n = 14, D2-IPSC: n = 17). These observations could not be explained by intrinsic receptor-GIRK coupling properties, differences in the timing of pre-synaptic exocytotic release, or dendritic filtering. The variability in the decay of alpha2-IPSCs significantly correlated to the amount of noradrenaline released as increasing the stimulation intensity driving release extended the duration of the alpha2-IPSC by 225% at maximum stimulations (n = 15 cells). This suggested pooling of noradrenaline in the extrasynaptic space prolonged alpha2-receptor transmission. D2-IPSCs, in contrast, had a consistent time course of decay regardless of the amount of transmitter released (n = 12 cells). Additional experiments determined that efficient reuptake through dopamine reuptake transporters (DATs) limited the pooling of dopamine to maintain the temporal fidelity of dopamine transmission. The function effects of the differences in clearance mechanisms across catecholamine synapses may determine the range and duration over which dopamine and noradrenaline can signal.

Title: Augmented latent inhibition and lower seizure threshold in protein interacting with C kinase (PICK1) knock-out mice

Authors: *H. M. ARNOLD[1], P. YANG[1], S. GLASS[1], R. L. HUGANIR[2], K. RHODES[1], A. DUNNAH[1];
[1]Neurol. Res., Biogen Idec, CAMBRIDGE, MA; [2]Johns Hopkins Univ. Sch. of Med. and Howard Hughes Med. Inst., Baltimore, MD

Abstract: Protein interacting with C kinase (PICK1) plays a critical role in synaptic plasticity through the regulation of trafficking and posttranslational modification of interacting proteins. One such protein is metabotropic glutamate receptor 7 (mGluR7), which is widely expressed on

presynaptic terminals of neurons throughout the brain and is proposed to regulate neurotransmitter release. mGluR7-deficient mice displayed spatial working memory deficits and delayed extinction of conditioned fear, and also were hypersensitive to proconvulsive pentylenetetrazole (PTZ) (Holscher et al., 2004, Callaerts-Vegh et al.k, 2006, Sansig et al., 2001). Both learning and memory deficits and convulsant effects could be replicated by uncoupling PICK1 from mGluR7a through mutation of PDZ-ligand motif of mGluR7a, which suggested that the mGluR7a-PICK1 interaction is essential for mGluR7a-associated receptor signaling and targeting (Bertaso F, et al., 2008; Zhang C, et al., 2008). In the present study we further examined the role of PICK1 in synaptic plasticity by examining the behavior of PICK1 knockout (KO) mice in two paradigms; latent inhibition of conditioned fear and the PTZ-induced seizure threshold test. Homologous and heterologous PICK1 KO mice and their wild-type littermates were tested at six months of age. Latent inhibition (LI) is believed to share a common molecular requirement as fear extinction and was tested in this study by fear pairing of white-noise and foot shock. LI refers to the observation that animals presented with non-reinforced pre-exposure to a stimulus (white noise) will acquire a lower level of conditioned fear relative to animals without the stimulus pre-exposure. LI was observed in the wild-type animals as expected in this experiment. PICK1 KO mice showed an even greater effect of the pre-exposure or enhanced latent inhibition relative to the wild-type mice. Seizure threshold was assessed in the PTZ-induced seizure model, and PICK1 KO mice exhibited a lower seizure threshold compared to wild-type animals. Taken together these results are consistent with the literature that indicates that PICK1 is crucial for mGluR7-associated synaptic plasticity.

Abstract: Altered neuronal synaptic plasticity, which is regulated by glutamate receptor trafficking, including calcium homeostasis are emerging pathophysiological features of several neurodegenerative and neuropsychiatric diseases. Changes in the trafficking of AMPA receptors can alter intracellular calcium levels and signaling at synapses. Here, we report that PICK1 plays an essential role in regulating the trafficking of GluR2 AMPA receptors in order to maintain synaptic plasticity and calcium homeostasis. We found that PICK1 inhibitors stabilize synaptic GluR2 receptors resulting in decreased AMPA-mediated calcium influx in cultured primary hippocampal neurons. Additionally, neurons lacking the PICK1 protein also show significant stabilization of GluR2 at synapses as well as a reduction in AMPA-mediated calcium influx. Moreover, PICK1 inhibitors inhibited long term depression in hippocampal slices. These findings suggest that pharmacological disruption of PICK1-GluR2 interaction can stabilize AMPA receptors at synaptic sites resulting in efficient preservation of synaptic plasticity and structural integrity. Therefore, PICK1-GluR2 pathway constitutes a potential therapeutic target for the development of novel treatments for neurological diseases.

Title: Soluble amyloid β-enhanced LTD in rat dentate gyrus of hippocampus is mGluR1/5-dependent and involves activation of p38MAPK, STEP and caspase-3

Authors: *L. CHANG, X. CHEN, R. LIN, J. HU, Q. WANG;
Physiol., Ningbo University, Med. Sch., Zhejiang, China

Abstract: Accumulation of amyloid beta (Aβ) protein is a key pathogenic element of Alzheimer's disease. It is reported that the Aβ-induced impairments in synaptic plasticity (LTP and LTD) coincides with memory decline and dementia. Although Aβ-induced inhibition of hippocampal long-term potentiation (LTP) has been intensively investigated, the underlying mechanism of Aβ-enhanced long-term depression (LTD) is not clear. Here, we report that acute exposure of rat hippocampal slices to soluble Aβ enhances LTD induced by sub-threshold low frequency stimulation (1Hz for 3 min, 180 pulses) in granule cells of dentate gyrus. Application of LY341495 (a non-selective Group I/II mGluR antagonist) completely block Aβ-enhanced LTD, whereas D-AP5 (a not selective NMDAR antagonist) has no effect on Aβ-enhanced LTD compared with untreated controls. In addition, Aβ-enhanced LTD is occluded by pre-application of 5-dihydroxyphenylglycine (DHPG), a Group1 mGluR (mGluR1/5) agonist, suggesting Aβ-enhanced LTD depends on mGluR1/5 but not NMDAR. We also report here that p38 mitogen-activated protein kinase (p38MAPK) inhibitor SB203580 and postsynaptic protein tyrosine phosphatase (PTP) inhibitors phenylarsine oxide (PAO) and sodium orthovanadate prevent the inhibitory effect of Aβ on LTD. The possible PTPs involved in Aβ-enhanced LTD could be striatal-enriched protein tyrosine phosphatase (STEP) because Aβ-enhanced LTD occludes a small LTD induced by STEP activator MG132 alone. Application of either non-selective caspase inhibitor Z-VAD-FMK or caspase-3 selective inhibitor Z-DEVD-FMK prevents Aβ-enhanced LTD, suggesting capase-3 is also necessary for the facilitatory effect of Aβ on LTD. However, neither tumor necrosis factor-α converting enzyme (TACE) inhibitor TAPI-2 nor mammalian target of Rapamycin (mTOR) inhibitor Rapamycin prevents the enhancement of Aβ on LTD. Therefore, we conclude that soluble Aβ enhances LTD in hippocampal dentate gyrus region, and the facilitatory effect of Aβ on LTD depends on mGluR1/5, p38MAPK, STEP and caspase-3 activation.

Title: Asymmetric dendritic spine dynamics in the apparently symmetric long-lasting synaptic plasticity phenomena after repeated LTP/LTD inductions

Authors: S. HASEGAWA, Y. OE, K. TOMINAGA-YOSHINO, *A. OGURA;
Osaka Univ., Suita/Osaka, Japan

Abstract: Memory is one of the most important functions of the brain. Instantaneously acquired memory becomes long-lasting through the process called consolidation. But the cellular mechanisms of consolidation remain unclear, since the cellular correlate of consolidation is elusive. A currently prevailing view assumes that late-phase LTP accompanying morphological changes in dendritic spines is the in vitro reproduction of consolidation, but longevity of those changes is uncertain. We previously showed in the organotypic slice cultures of the rodent hippocampus that three repeated inductions of LTP and LTD by chemical means led to slowly developing long-lasting synaptic enhancement and suppression coupled with synapse formation and elimination, respectively. Naming these phenomena RISE (Repetitive LTP-Induced Synaptic Enhancement) and LOSS (LTD-repetition-Operated Synaptic Suppression), we propose these as the in vitro reproduction of memory consolidation suitable for the analysis of the cellular mechanisms of consolidation.
Our previous studies showed that the increase in net spine number in RISE is resulted from 2-step processes; 1) increased spine dynamics after the third LTP (increase in rates of both spine generation and retraction) followed by 2) earlier returning of the retraction rate to its basal level. In the present study we examined whether or not LOSS would follow symmetric 2-step processes. Using sequential confocal imaging (1-day or 5-day intervals) on the slice cultures from Thy1-YFP H-line transgenic mice that express YFP in the CA1 pyramidal neurons, we found that three inductions of chemical LTD by DHPG led to an increased rate of spine retraction leaving the rate of generation uninfluenced, resulting a decrease in net spine number. Single induction of LTD caused no apparent changes in both rates as judged from 1-day interval imaging. We showed previously that the spine number increase in RISE occurred preferentially in the dendritic segments having low pre-existing spine density. In LOSS, however, the spine number decrease relatively homogeneously irrespective to pre-existing spine density. These results reveal that RISE and LOSS proceed non-symmetrically, although the effects are apparently symmetric.

Title: Effects of a clinically-used opioid analgesic on dissociable forms of long-term depression in the dorsal striatum

Authors: *B. K. ATWOOD[1], D. KUPFERSCHMIDT[2], W. XIONG[2], D. LOVINGER[2];
[1]LIN, [2]NIAAA, Rockville, MD

Abstract: The dorsal striatum is a brain region that is critically involved in action selection and habit formation and as such plays an important role in addiction to drugs of abuse. Opioid peptides, their target receptors and the peptidase enzymes that are responsible for terminating their actions are abundantly expressed in this brain region. Many components of this endogenous opioid system are modulated by opioid analgesics as well as other drugs of abuse. We have previously demonstrated that a brief exposure to mu opioid receptor agonists produces long-term depression (OP-LTD) of excitatory inputs on to medium spiny neurons in the dorsal striatum. In addition we have shown that endogenously released opioid peptides are also able to induce OP-LTD. Interestingly these endogenously released opioids also exert their effects through mu and other opioid receptors. We thus explored whether agonists for other opioid receptors could also promote OP-LTD of glutamatergic transmission in the dorsal striatum. We also sought to determine what effect a commonly abused prescription painkiller, oxycodone, would have on plasticity mediated by these other opioid receptors as well as cannabinoid receptors. We found that agonists of mu and delta opioid receptors could each induce OP-LTD through their respective target receptors. Despite each receptor being able to induce OP-LTD upon activation, the two receptors were not able to occlude one another's effects. Furthermore, mu OP-LTD was mutually occlusive with endocannabinoid-dependent LTD, whereas delta OP-LTD was not. These data suggest that the two receptors are acting at different synapses or via distinct mechanisms. A single in vivo exposure to the opiate analgesic, oxycodone, disrupts the expression of mu OP-LTD and endocannabinoid LTD, but not delta OP-LTD. This disruption lasted for 2 days and was paralleled by a performance deficit in a rotarod training paradigm. These data demonstrate a novel form of long-lasting synaptic plasticity in the dorsal striatum that

is induced by a brief exposure to opioid peptides that has relevance for the consequences of opiate analgesic use.

Title: Role of DGKζ in the regulation of PKCα activity and cerebellar Purkinje cell synapses

Authors: *D. LEE[1,2], K. KIM[2], Y. KIM[1], Y. YAMAMOTO[1], E. KIM[2], K. TANAKA-YAMAMOTO[1];
[1]Ctr. for Functional Connectomics, KIST, Seoul, Korea, Republic of; [2]Dept. of Biol. Sci., KAIST, Daejeon, Korea, Republic of

Abstract: Long-term synaptic plasticity is triggered by synaptic stimulation, and activation of many signals is implicated in such synaptic plasticity, so that molecules working negatively on these signals must control signaling activities and synaptic plasticity. In cerebellar Purkinje cells, activation of protein kinas C (PKC), specifically PKCα, is well known to be one of key factors for triggering long-term synaptic depression (LTD). However, the negative regulators of PKC are not yet investigated. Diacylglycerol kinase ζ (DGKζ), which is strongly expressed in Purkinje cells, has been reported in a study using HEK293 cells to negatively regulate PKCα via binding with PKCα and metabolizing diacylglycerol, a PKCα activator. Further, our previous study demonstrated that DGKζ can be targeted to the excitatory synapses by interacting with PSD-95 family proteins (EMBO J, 2009, 28:1170). These studies raise a possibility that DGKζ regulates postsynaptic PKCα activation and consequently cerebellar LTD. In this study, we tested the role of DGKζ in the cerebellar LTD by using DGKζ knockout mice. First of all, we looked at the morphology of Purkinje cells. Although the Sholl analysis showed that distal dendritic trees in DGKζ knockout mice are more complex than those in their wild-type littermates, densities of dendritic spines were unaltered, so that deficiency of DGKζ seems to have less impact on synaptic morphology. We then recorded synaptic transmission at synapses between parallel

fibers and Purkinje cells. Surprisingly, LTD was blocked in the DGKζ knockout mice. It is unlikely that increase in basal PKCα activation caused by deficiency of DGKζ already induced LTD and that further induction of LTD was occluded, because basal synaptic transmission was unaltered in the DGKζ knockout mice. To investigate the PKCα activation, we used chemical LTD stimulation and observed translocation of endogenous PKCα from cytosol to the plasma membrane in Purkinje cell soma. This analysis revealed that PKCα activation is indeed enhanced in DGKζ knockout mice. One possible interpretation of these results is that hyperactivation of PKCα caused by deficiency of DGKζ leads to the impairment of LTD induction. In this case, this study brings up an idea that signals need to be precisely regulated via balancing between positive and negative regulators for triggering LTD. This idea is in part consistent with the leaky integrator property of LTD induction described in our previous study (Neuron, 2007, 54:787).

Title: Neurotensin induces long-term depression of dopamine D2 receptor-mediated inhibitory postsynaptic currents in substantia nigra dopamine neurons

Authors: *E. PICCART[1], M. J. BECKSTEAD[2];
[2]Physiol., [1]UTHSCSA, San Antonio, TX

Abstract: Midbrain dopamine (DA) neurons express high levels of D2-type autoreceptors ($D2R_{auto}$) on their cell bodies and dendrites. Iontophoretic application of DA or electrically evoked release of DA activates these autoreceptors and produces an outward current or an inhibitory postsynaptic current (IPSC), respectively. Prolonged activation of $D2R_{auto}$ induces long-term depression (LTD) of DA-mediated currents, an effect that is blocked by chelating calcium postsynaptically. Midbrain DA neurons receive dense innervation from neurotensin (NT) fibers. Activation of the predominant NT receptor 1 (NTR1) antagonizes D2 DA receptors via allosteric receptor/receptor interactions as well as second messenger signaling cascades. For

instance, NTR1 activation is shown to cause $D2R_{auto}$ internalization through PKC activation. Here, we addressed the effect of NT on $D2R_{auto}$-mediated currents using patch clamp electrophysiology in substantia nigra pars compacta DA neurons. Bath application of the active fragment NT_{8-13} (30, 100, 300 nM) depressed outward currents evoked by iontophoretic application of DA. This depression only persisted over time (30 min) when intracellular calcium was chelated using a high concentration of BAPTA (10 mM) in the pipette. Bath perfusion of the PKC-inhibitor staurosporine (1 M) did not affect NT-induced depression of outward currents. Bath application of NT_{8-13} also induced LTD of $D2R_{auto}$-mediated IPSCs, and this occurred independent of postsynaptic calcium chelation. We thus show a novel form of NT-induced synaptic plasticity in midbrain DA cells that appears to be independent of available intracellular calcium. The net result of this NT-induced depression of an inhibitory signal would be an increase in the excitability of DA neurons which could subsequently affect DA-mediated behaviors and disorders.

Title: The role of X-linked mental retardation protein, BRAG1, in synaptic function

Authors: *J. C. BROWN[1], L. ZHONG[1], A. PETERSEN[1], R. WALIKONIS[2], N. Z. GERGES[1]; [1]Cell Biol, Neurobio. & Anat., Med. Col, Wisconsin, Milwaukee, WI; [2]Physiol. and Neurobio., Univ. of Connecticutt, Storrs, CT

Abstract: Learning disorders often result from disrupted AMPA receptor trafficking. X-linked mental retardation (XLMR) is a developmental disorder characterized by significant limitations in cognitive function, and the ability to perform basic daily tasks. Recently, mutations of a post-synaptic density (PSD) protein, BRAG1, were identified as a cause of XLMR (Shoubridge et al., 2010).
Here we report that BRAG1 is sufficient to increase the synaptic expression of recycling GluA2-

containing AMPA receptors in hippocampal slice cultures. This enhancement was blocked with an interfering peptide designed to prevent interactions with the PDZ-binding domain. Moreover, a c-terminal truncation lacking the PDZ-binding domain failed to produce an increase, indicating that BRAG1 PDZ interactions facilitate synaptic GluR2 expression.
BRAG1 guanine nucleotide exchange factor (GEF) activity was shown by Shoubridge et al. to be impaired in XLMR patients. We report that BRAG1 GEF activity is required for long-term depression. In fact, blocking BRAG1-GEF activity drastically increases AMPAR-mediated synaptic transmission after prolonged expression, suggesting AMPAR accumulation over time in the absence of GEF-mediated internalization. Together, these results indicate a critical role in synaptic function for BRAG1 involving both insertion and removal of AMPARs, providing new insight into mechanisms underlying learning disabilities.

Title: Regional variations in phosphodiesterase and adenylyl cyclase activity contribute to the differential expression of adenosine A1 receptor-mediated synaptic plasticity in hippocampal areas CA1 and CA2

Authors: *D. A. CARUANA, S. M. DUDEK;
NIEHS/NIH, Research Triangle Park, NC

Abstract: Adenosinergic signaling in the hippocampus regulates both synaptic function and behavior. We have shown previously that adenosine A1 receptors (A1Rs) mediate bidirectional changes in synaptic efficacy at Schaffer collateral (SC) inputs to CA2 that are not seen at CA1 synapses. Such differential sensitivity to A1R agonists and antagonists across hippocampal subfields likely reflects differences in both the regional and developmental expression of A1Rs and associated downstream effectors. Indeed, although staining for A1R protein is uniform across the rodent hippocampus early in development, it changes dramatically after postnatal day 28, with staining increasing in CA2 and decreasing in CA1 as animals mature. Our data using stimulation of A1Rs support this developmental pattern of staining: we have shown that low

concentration of A1R agonists induce long-term depression (LTD) in SC inputs to both CA1 and CA2 in slices obtained from juvenile rats, but only in CA2 in adult slices. Surprisingly, effects of A1R antagonists on synaptic responses do not follow a similar developmental pattern: inhibiting A1Rs potentiates EPSCs in CA2, but not in CA1, regardless of age. To determine the key intracellular signals underlying these regional differences in A1R-mediated synaptic plasticity, we recorded whole-cell EPSCs from pyramidal neurons in juvenile rat CA2 and CA1 evoked by stimulating the SCs. Bath-application of the selective A1R agonist CCPA (100nM) for 5 min induced LTD of EPSCs in both CA2 and CA1 that persisted for 60 min. The CCPA-mediated depression relied on neither NMDA receptors nor p38 MAP kinase activation, and did not require synaptic stimulation for its induction. We next tested whether inhibiting cAMP degradation would prevent LTD induced by CCPA. Surprisingly, the phosphodiesterase (PDE) inhibitor rolipram (10μM) blocked A1R-mediated LTD in CA1, but not in CA2, suggesting that the PDE subtypes or basal PDE activity levels in CA1 differ considerably from those in CA2. We have noted that several PDE isoforms are differentially expressed in CA1 or CA2 (e.g. Pde8b in CA1). Finally, we examined whether the selective potentiation in the juvenile CA2 is due to downstream targets of A1Rs, including some adenylyl cyclases that are highly expressed in CA2 (e.g., adcy1, 5 or 6). We found that forskolin (10μM), which stimulates adenylyl cyclases directly, potentiated EPSCs in CA2, but not in CA1. Together, these data indicate that the heightened sensitivity of the juvenile CA2 in response to A1R antagonists is a reflection of the differential expression of both adenylyl cyclases and phosphodiesterases rather than enrichment of the A1 receptors.

Title: Chronic stress impairs α_1-adrenergic receptor-induced endocannabinoid ltd in the dorsal raphe nucleus

Authors: *S. HAJ-DAHMANE, J. WANG, R.-Y. SHEN;
SUNY @ Buffalo, BUFFALO, NY

Abstract: In the dorsal raphe nucleus (DRn), activation of alpha 1-adrenergic receptors (α_1-ARs) exerts a tonic activation of DRn serotonin (5-HT) neurons and plays a crucial role in regulating arousal and the behavioral responses to stress. However, the precise effects of these receptors on glutamatergic synaptic transmission to DRn 5-HT neurons and how chronic exposure to stress alters α_1-ARs-induced modulation of the synaptic function in the DRn remain unknown. In the present study, we examined the impact of the activation of α_1-ARs on the strength and plasticity of glutamate synapses of putative DRn 5-HT neuron in control rats and after chronic exposure to restraint stress. We found that in control animals, activation of α_1-ARs elicited a postsynaptic membrane depolarization/inward current and long-term depression (LTD) of excitatory synaptic transmission onto putative DRn 5-HT neurons. The α_1-AR-LTD revealed that it was mediated by a decrease in glutamate release and signaled by retrograde endocannabinoid (eCB) messengers. In addition , we found that exposure to chronic (7 days) restraint stress profoundly reduced the magnitude of α_1-AR-LTD, without altering the amplitude of α_1-receptor-induced inward current. The stress-induced impairment of α_1-AR-LTD was not mediated by an alteration α_1-AR function but rather by a down regulation of presynaptic CB1 receptors. Together, our results demonstrate that noradrenergic tone in DRn control synaptic plasticity by recruiting eCB signaling. They also provide the first evidence that chronic stress alters eCB-mediated synaptic plasticity in the DRN which could represent a potential mechanism underlying stress homeostasis.

Title: Effects of anomalous diffusion on synaptic plasticity

Authors: *T. MARINOV[1], F. SANTAMARIA[2];
[1]Univ. of Texas at San Antonio, San Antonio, TX; [2]UTSA Neurosciences Inst., Univ. of Texas, San Antonio, TX

Abstract: We have experimentally and computationally demonstrated that intracellular dendritic diffusion of soluble signals can be anomalous in Purkinje and pyramidal cells. Dendritic spines cause anomalous diffusion by acting as traps that transiently capture diffusing molecules. Anomalous diffusion is characterized by a mean square displacement (msd) of a diffusing particle that follows a power law (msd ~ t^a). Here we study the role of anomalous diffusion in the spatial and temporal expression of long term depression (LTD) of the parallel fiber to Purkinje cell synapse. LTD is mediated by a positive feedback loop involving [Ca2+], PKC and MAPK. While [Ca2+] does not undergo anomalous diffusion, PKC and MAPK are large proteins susceptible to molecular trapping by spines. Using our recently developed fractional integration toolbox we solve the anomalous diffusion equation based on fractional calculus. We have implemented a simplified LTD model of coupled fractional diffusion-reaction equations for [Ca2+], PKC and MAPK with non-constant diffusion coefficients and reaction rates for various fractional orders and spatial and temporal distributions. Fractional diffusion results in longer activation times for the PKC-MAPK positive feedback loop. Once activated, PKC and MAPK stay activated longer, implying a lower [Ca2+] activation threshold. Thus, anomalous diffusion of signaling molecules along dendrites could affect the sensitivity of expression of synaptic plasticity.

Title: Activation of synaptic group II mGluRs induces long-term depression at GABAergic synapses in CNS neurons

Authors: *Y.-W. LIU, Z.-Q. TANG, W. SHI, E. DINH, W. HAMLET, R. CURRY, Y. LU; Northeast Ohio Med. Univ., Rootstown, OH

Abstract: Metabotropic glutamate receptor (mGluR)-dependent homosynaptic long-term depression (LTD) has been studied extensively at glutamatergic synapses in the CNS. However, much less is known about heterosynaptic long-term plasticity induced by mGluRs at inhibitory synapses. Here we report that pharmacological or synaptic activation of group II mGluRs (mGluR II) induces LTD at GABAergic synapses in neurons of the chicken cochlear nucleus.

Coefficient of variation and failure rate analysis revealed that the LTD was expressed presynaptically. The LTD requires presynaptic spike activity, but does not require the activation of NMDA receptors. The classic cAMP-dependent protein kinase A signaling is involved in the transduction pathway. Interestingly, mGluR II did not modulate the excitatory glutamatergic transmission of NM neurons. Blocking mGluR II increased spontaneous GABA release, indicating the presence of tonic activation of mGluR II by ambient glutamate. Synaptically released glutamate induced by electrical stimulations that concurrently activated both the glutamatergic and GABAergic pathways resulted in significant and constant suppression of GABA release at various stimulus frequencies (3.3, 100, and 300 Hz). Strikingly, low frequency stimulation (1 Hz, 15 min) of the glutamatergic synapses induced heterosynaptic LTD of GABAergic transmission without altering glutamatergic transmission, and the LTD was blocked by mGluR II antagonist, indicating that activation of synaptic mGluR II induced the LTD. This novel form of long-term plasticity in the avian auditory brainstem may play a role in the development as well as in temporal processing in the sound localization circuit.

Title: Intracellular mechanisms responsible for serotonin-mediated reversal of metabotropic glutamate receptor-mediated long-term depression (mGluR-LTD) in wild-type and Fmr1 KO mouse hippocampus

Authors: L. T. COSTA[1], C. M. BONACCORSO[2], S. A. MUSUMECI[2], M. V. CATANIA[3,2], *L. CIRANNA[4];
[1]Dept. of Clin. and Exptl. Med., Univ. of Messina, Messina, Italy; [2]Lab. of Neurobiol., IRCCS Oasi Maria Santissima, Troina (EN), Italy; [3]Inst. of Neurolog. Sci. (ISN), Natl. Res. Council (CNR), Catania, Italy; [4]Dept. di Scienze Bio-Mediche, Univ. Di Catania, Catania, Italy

Abstract: We have shown that activation of serotonin type 7 (5-HT7) receptors prevents metabotropic glutamate receptor-mediated endocytosis of AMPA receptors and subsequent long-term depression (mGluR-LTD) in the hippocampus of wild-type (WT) and Fmr1 KO mice, a

mouse model of Fragile X Syndrome (FXS) in which mGluR-LTD is abnormally enhanced (Costa et al., Biol. Psych. 2012, 72:924-933). 5-HT7 receptors are classically coupled to stimulation of adenylate cyclase and protein kinase A (PKA) but other signalling pathways have been suggested, including the kinases Akt and glycogen synthase kinase 3 (GSK3).
To identify the intracellular mechanisms involved in 5-HT7-mediated reversal of mGluR-LTD, we recorded AMPA receptor-mediated excitatory post-synaptic currents ($EPSC_{AMPA}$) from CA1 pyramidal neurons under patch clamp on hippocampal slices from WT mice. Application of the group-I mGluR agonist DHPG induced a long-term depression (mGluR-LTD) of $EPSC_{AMPA}$. When DHPG application was followed by application of either 5-HT or 8-OH DPAT (a mixed 5-HT1A/5-HT7 agonist), DHPG-induced mGluR-LTD was completely reversed. 5-HT-mediated reversal of mGluR-LTD persisted in the presence of intracellular cAMPS-Rp (a cAMP analogue which binds PKA without activating it) and was not mimicked by 8-Br-cyclic AMP.
When lithium was included in the intracellular solution at a concentration (20 mM) that inhibits GSK3, the amount of DHPG-induced mGluR-LTD was not significantly different from control conditions, but the reversal effect of 8-OH-DPAT application on mGluR-LTD was blocked. These results indicate that reversal of mGluR-LTD by 5-HT7 receptor activation is not mediated by the cAMP/PKA pathway and likely involves inhibition of GSK3 signalling.
In Fmr1 KO mice, GSK3 activity is abnormally elevated and lithium treatment was shown to reverse abnormal phenotypes typical of FXS (Min et al., 2009, Neuropharmacol. 56: 463-72; Guo et al., 2012, Hum. Mol. Genet. 21: 681-91). Consistently, we suggest that activation of 5-HT7 receptors, by inhibiting GSK3 activity, might correct the pathological features in Fmr1 KO mice and might be considered as a novel therapeutic strategy for FXS.

Title: Investigations of the role of eIF4E/eIF4G interactions and S6K1 in protein synthesis-dependent hippocampal synaptic plasticity

Authors: *E. SANTINI[1], T. HUYNH[2], S. KOO[3], E. KLANN[1];
[1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]Ctr. for Neural Sci., [3]New York Univ., New York City, NY

Abstract: Memories are encoded and stored through persistent, activity-dependent changes at individual synapses. Long-term depression (LTD) is an activity-dependent decrease in synaptic efficacy that can be induced in hippocampal area CA1 by pharmacological application of the selective group I metabotropic glutamate receptor (mGluR) agonist 3,5-diyhroxyphenylglycine (DHPG). Current evidence indicates that mGluR-LTD requires new protein synthesis, achieved through activation of mammalian target of rapamycin complex 1 (mTORC1) signaling pathway. The mTORC1 cascade regulates cap-dependent translation by modulating both initiation and elongation phases. Upon activation, mTORC1 induces phosphorylation of 4E-binding protein (4E-BP), thereby releasing the cap-binding translation factor eIF4E so that it can bind to eIF4G, which recruits other initiation factors (eIF4B and eIF4A) to form the initiation complex eIF4F. mTORC1 also activates p70 S6 kinase 1 (S6K1), which in turn phosphorylates eIF4B and the elongation factor kinase eEF2. Phosphorylation of eIF4B promotes the helicase activity of eIF4A and phosphorylation of eEF2 kinase regulates via eEF2 the translocation step of elongation. Thus, mTORC1-dependent activation of 4E-BP and S6K1 is a crucial molecular event that modulates cap-dependent protein synthesis.
Recently, two new compounds termed 4EGI-1 and PF-4708671 has been identified that inhibit the downstream effectors of mTORC1. 4EGI-1 blocks the association eIF4E with eIF4G, thereby disrupting the initiation phase of translation. Whereas, PF-4708671 inhibits the activity of S6K1, thus blocking initiation and elongation phases of translation.
Here, we have investigated the impact of 4EGI-1 and PF-4708671 on hippocmapal mGluR-LTD. We have found that neither 4EGI-1 nor PF-4708671 alone impact hippocampal mGluR-LTD. In contrast, we found that hippocampal slices treated with both 4EGI-1 and PF-4708671 attenuates mGluR-LTD. These results are consistent with the attenuation of mGluR-LTD by rapamycin, which by blocking mTORC1, inhibits both 4E-BP and S6K1. Our findings indicate that concomitant activation of eIF4F and S6K1 are required for mGluR-LTD and that 4EGI-1 and PF-4708671 are effective tools for examining specific translational control mechanisms required for long-lasting synaptic plasticity. Moreover, our findings suggest that 4EGI-1 and PF-4708671 have the potential as therapeutics for cognitive disorders, including autism spectrum disorders, that are associated with enhanced eIF4E/eIF4G interactions and increased S6K activity.

Title: Epigenetic regulation of synaptic plasticity and epilepsy in tuberous sclerosis complex

Authors: *T. BASU, K. O'RIORDAN, A. KIRCHNER, B. SCHOENIKE, A. ROOPRA; Univ. of Wisconsin-Madison, Madison, WI

Abstract: Tuberous Sclerosis Complex (TSC) is a genetic disorder that affects 1 in 6,000 people and it is characterized by epilepsy, benign tumor formations throughout the body and brain, and cognitive deficits (Curatolo, P., 2002; Crino, P.B. 2006). TSC is caused by a mutation in either *TSC1* or *TSC2* genes resulting in heightened mammalian target of Rapamycin (mTOR) signaling (van Slegtenhorst, 1997). Mammalian TOR is a protein kinase that regulates activity dependent translation of dendritic proteins required for synaptic plasticity in the hippocampus. Persistent mTOR activation in TSC leads to heightened dendritic protein synthesis and aberrant synaptic plasticity deficits (Tang, S.J., 2002; Hou,L., 2004).

Heterozygous TSC2 mutants, ($TSC2^{+/-}$) exhibit abnormal long term potentiation (LTP) and long term depression (LTD) compared to Wild Type (WT) mice: whereas a 1X Theta Burst Stimulation elicits short term potentiation in WT mice, this stimulation produces LTP in $TSC2^{+/-}$ mice. In contrast to WT mice, adult $TSC2^{+/-}$ mice display rapamycin insensitive metabotropic glutamate receptor (mGluR) mediated LTD. Epileptiform activity in hippocampal slices can be induced through prolonged incubation with the group 1 mGluR agonist, DHPG. Recordings from the CA3 stratum pyramidale region of the hippocampus show that $TSC2^{+/-}$ mice have greater ictal-like activity (burst durations lasting longer than 2 seconds with greater than 2 Hz of intraburst frequency) and more long duration burst activity compared to WT mice.

From a whole genome expression analysis of cortical samples collected from TSC patients and non-TSC patients, we found that the majority of gene expression changes between the two populations can be explained by epigenetic mechanisms. Using drugs that modify chromatin structure through histone deacetylation and demethylation, we find that the aberrant forms of LTP, LTD and bursting phenotypes present in $TSC2^{+/-}$ are ameliorated. Our findings are the first to describe epigenetic mechanisms influencing the synaptic plasticity alterations in TSC. This novel study opens up the possibility of using clinically available epigenetic modifying drugs to treat the cognitive, synaptic plasticity and epilepsy manifest in TSC patients.

Title: AMPA receptor pHluorin-GluA2 reports NMDA receptor-induced intracellular acidification in hippocampal neurons

Authors: *M. A. RATHJE[1], H. FANG[2], J. L. BACHMAN[2], U. GETHER[1], R. L. HUGANIR[2], K. L. MADSEN[1];
[1]Dept. of Neurosci. and Pharmacol., Copenhagen, Denmark; [2]Johns Hopkins, Baltimore, MD

Abstract: NMDA receptor activation promotes endocytosis of AMPA receptors, which is an important mechanism underlying LTD (long term synaptic depression). The pH-sensitive GFP variant pHluorin fused to the N-terminus of GluA2 (pH-GluA2) has been used to assay NMDA-mediated AMPA receptor endocytosis and recycling. Here, we demonstrate that in somatodendritic regions of hippocampal neurons a large fraction of the fluorescent signal originates from intracellular pH-GluA2, and that the decline in fluorescence in response to NMDA and AMPA primarily describes an intracellular acidification, which quenches the pHluorin signal from intracellular receptor pools. Neurons expressing an ER-retained mutant of GluA2 (pH-GluA2 ΔC49) displayed a larger response to NMDA than neurons expressing wild type pH-GluA2. A similar NMDA-elicited decline in pHluorin signal was observed by expressing cytosolic pHluorin alone without fusion to GluA2 (cyto-pHluorin). Intracellular acidification in response to NMDA was further confirmed by using the radiometric pH-indicator carboxy-SNARF-1. The NMDA-induced decline was followed by rapid recovery of the fluorescent signal from both cyto-pHuorin and pH-GluA2. The recovery was sodium-dependent and sensitive to Na+/H+-exchanger (NHE) inhibitors. Moreover, recovery was prolonged by shRNA-mediated knock-down (KD) of the GluA2 binding PDZ-domain protein PICK1.

Interestingly, the accelerating effect of PICK1 KD on the fluorescent recovery was eliminated in the presence of the NHE1 inhibitor zoniporide. Our results challenge the applicability of pH-GluA2 for studying AMPA receptor trafficking and suggest a role of PICK1 in regulating intracellular pH via modulation of NHE activity.

Title: Striatopallidal long-term synaptic plasticity

Authors: *R. HERNÁNDEZ, SR, M. A. ARIAS-GARCÍA, J. E. PEREZ-ORTEGA, E. GALARRAGA, J. BARGAS;
UNAM, México, Mexico

Abstract: Long-term synaptic plasticity (LTSP) has been proposed as a mechanism for information storage at both excitatory and inhibitory synapses. It is posited as the cellular/molecular basis of memory. The basal ganglia are involved in the storage of procedural memories. However, current research of LTSP in the basal ganglia has almost completely been restricted to the corticostriatal synapse. Nonetheless, it would be strange that all memory process in these subcortical nuclei depend on a single synapse. Thus, our laboratory has demonstrated that complex LTSP phenomena are present in striatonigral inhibitory synapses (direct pathway of the basal ganglia). Here, we now show, by using whole cell patch clamp recordings from pallidal neurons (GPe) in rat brain slices, that the striatopallidal inhibitory synapse (indirect pathway of the basal ganglia) exhibits LTSP in the form of long term synaptic depression (LTD).

Metabotropic receptors such as muscarinic and glutamatergic are necessary to induce this phenomenon via the production of endocannabinoids synthesis. However, once induced, the mechanism that stabilize and sustain LTD does not longer depend on endocannabinoids.

Title: N-methyl-d-aspartate receptor (nmdar)-activated kinases in presynaptic long-term depression (ltd)

Authors: *K. R. GOPAUL[1], X.-L. ZHANG[2], P. STANTON[3];
[1]New York Med. Col., New York, NY; [2]Cell Biol. & Anat., New York Med. Col., Valhalla, NY; [3]Cell Biol. & Anat., New York Med. Col., New York, NY

Abstract: *N*-methyl-D-aspartate receptors (NMDAR) and metabotropic glutamate receptors (mGluR) have independently been shown to play important roles in induction of long-term depression (LTD) of presynaptic transmitter release at a variety of hippocampal synapses. Postsynaptic NMDAR activation leads to generation of the intercellular messenger nitric oxide, which triggers presynaptic production of cyclic guanosine monophosphate (cGMP) that transiently depresses transmitter release. Activation of presynaptic group II mGluR, a G protein-coupled receptor (GPCR), releases Gα and Gβγ subunits that play distinct roles in the reduction of vesicle release. We have shown that increased [cGMP] evoked by NMDAR activation, combined with inhibition of adenylate cyclase (AC) by an inhibitory $G\alpha_{i,}$, induces LTD. The other G protein released after GPCR activation, Gβγ, regulates transient depression of neurotransmitter release by interacting with the C-terminus of the SNARE (Soluble N-ethylmaleimide-Sensitive Factor Attachment Protein Receptor) protein, Synaptosomal Associated Protein 25kD (SNAP-25). We hypothesize that three events, elevated [cGMP], inhibition of PKA by $G\alpha_{i}$, and binding of Gβγ to the C-terminus of SNAP-25 are all necessary for the induction of LTD of vesicular neurotransmitter release. We monitored changes in release

mechanisms from distinct readily-releasable and reserve presynaptic vesicle pools, using electrophysiological recordings in the hippocampus of rodent brain slices and imaging fluorescent membrane dyes destaining via two-photon microscopy. By selectively inhibiting enzymes in the NMDAR or mGluRII biochemical pathways, we used the above techniques to determine the shared regulatory component of neurotransmitter release from Schaffer collateral presynaptic terminals in the CA1 region of hippocampal slices. Blockade of CaMKII activity with the selective inhibitors KN-62 (2 µM) or KN-93 (2 µM) partially inhibited LTD of both synaptic transmission and FM1-43 release from the sucrose-loaded readily-releasable vesicle pool elicited by bath application of NMDA (20 µM), but not mGluRII-LTD elicited by the mGluRII agonist DCG-IV (25 µM). These data suggest that a presynaptic component of NMDAR-dependent LTD depends on CaMKII activity, probably in the presynaptic terminal.

Title: Aging-associated immune dysregulation drives a shift in the direction of hippocampal synaptic plasticity and the ratio of proBDNF vs. mBDNF

Authors: *G. P. CORTESE, R. M. BARRIENTOS, S. F. MAIER, S. L. PATTERSON; Psychology & Neurosci., Univ. of Colorado, Boulder, BOULDER, CO

Abstract: Older individuals often experience precipitous declines in cognitive function after events (Ex. surgery, infection, or injury) that trigger activation of the peripheral immune system. Aging sensitizes the hippocampal inflammatory response to peripheral infection, increasing the

size and duration of the resulting spike in interleukin-1beta (IL-1β). We have previously demonstrated that in aging (24 month), but not in young (3 month) F344xBN rats, a peripheral immune challenge (i.p. injection of live E. coli) triggers an exaggerated elevation in hippocampal IL-1β, which in turn disrupts forms of long-term memory and synaptic plasticity known to be BDNF-dependent (Barrientos et al. 2006; Chapman et al., 2010).
Hippocampal memory processes are thought to involve shifts in the balance of LTP and LTD (long-term potentiation and depression of excitatory synaptic transmission). Numerous studies have shown that disruptions in hippocampal LTP (Barnes and McNaughton 1985), and enhancements of hippocampal LTD (Massey & Bashir 2007) are strongly correlated with memory impairments. In addition, shifts in the direction of hippocampal synaptic plasticity have been reported in rodent models of neurodegenerative diseases associated with memory loss (Li et al., 2009).
Interestingly, BDNF modulates both LTP and LTD. BDNF is synthesized as a precursor protein (proBDNF), and cleaved to produce the mature BDNF protein isoform (mBDNF). Pro-BDNF binds preferentially to the pan-neurotrophin receptor p75NTR, activates apoptosis-related signaling pathways, and facilitates long-term depression (LTD) in the hippocampus. In contrast, mBDNF binds to TrkB receptors, promotes cell survival, and is required for some forms of long-term potentiation (LTP).
We have previously found that mBDNF, but not pro-, is significantly reduced in hippocampal synaptoneurosomes prepared from aged animals following an infection (Cortese et al., 2011) - an observation consistent with reduced theta burst L-LTP at Schaffer collateral-CA1 synapses in these animals (Chapman et al., 2010). Here, we report that the IL-1β -driven shift in the ratio between proBDNF and mature BDNF is also associated with enhanced LTD, and evidence of increased proBDNF - p75 receptor-ligand interactions. This work examines the functional role of endogenous BDNF protein isoforms in memory-related plasticity processes. It may also provide novel insights into the early stages of synaptic failure in a variety of disorders associated with dysregulated brain inflammatory responses (Ex. post-operative cognitive dysfunction, autoimmune diseases, depression, PTSD and some neurodegenerative disorders).

Title: Impairment of both NMDAR-dependent and mGluR-dependent long-term depression (LTD) in the hippocampus of a sortilin related receptor (SORCS3) deficient mouse model

Authors: *G. B. CHRISTIANSEN[1], T. BREIDERHOFF[3], A. NYKJAER[2], K. JENSEN[1,2], T. WILLNOW[3], M. M. HOLM[1];
[1]Dept. of Biomedicine, [2]Lundbeck Fndn. Res. Ctr. MIND, Dept. of Biomedicine, Aarhus Univ., Aarhus C, Denmark; [3]Max-Delbrueck-Centrum (MDC), Berlin, Germany

Abstract: SORCS3 is a member of the VPS10P-domain receptor family also known as the sortilins. So far, this receptor has been the most anonymous member whereas other members of the family are believed to be involved in synaptic plasticity and different disorders of the CNS. *In situ* hybridization analyses have previously showed that SORCS3 is strongly expressed in the CA1 of the hippocampus (Hermey et al., 2004, *J. of Neurochem.*) and consequently, we initiated electrophysiological analysis in this area on a SORCS3 deficient mouse model to investigate the role of this receptor in synaptic plasticity.
Extracellular field recordings of Schaffer collateral-pyramidal cell synapses in the CA1 area of the hippocampus were performed in an interface recording chamber. 400 µm thick coronal slices were prepared from age-matched wild-type (WT) and knockout (KO) animals. Young mice (P17-P21) were included in the long-term depression (LTD) analysis, and mature mice (P30-P60) were included in the long-term potentiation (LTP) analysis and paired-pulse recordings. NMDAR-dependent LTD was induced by a 20 min 1 Hz protocol, and the mGluR-dependent LTD was induced by an 18 min 1 Hz with paired-pulse (interstimulus interval at 50 ms) protocol. LTP was induced by a 2 x 100 Hz protocol. The slope of the field excitatory postsynaptic potential (fEPSP) was normalized to a 20 min baseline.
These data revealed that the SORCS3 protein has an essential role in synaptic plasticity. Both the NMDAR-dependent (WT: 83.6% ± 4.2%; KO: 99.2% ± 4.9%, $p < 0.05$) and mGluR-dependent LTD (WT: 78.3% ± 8.3%; KO: 98.1% ± 4.4%, $p < 0.05$) was impaired in the SORCS3 deficient mice. Early LTP was normal (WT: 158% ± 11.0%; KO: 143% ± 8.7%, $p > 0.05$) and paired-pulse analysis using interstimulus intervals of 25-300 ms revealed no obvious presynaptic defects in SORCS3 knockout mice ($p > 0.05$). Application of the $GABA_B$ receptor agonist baclofen increased the paired-pulse ratio equally in WT and KO mice ($p > 0.05$) from 180% to 206% in WT mice and from 184% to 200% in KO mice (interstimulus interval at 50 ms).
Based on these results, we conclude that the SORCS3 receptor is likely to play an essential postsynaptic role in NMDAR-dependent and mGluR-dependent LTD, probably through interactions with key proteins responsible for the internalization and/or retention of AMPA receptors during LTD. Based on the fEPSP profile during the LTD analysis, the retention of the AMPA receptors within intracellular compartments appears to be affected the most by the absence of the SORCS3 receptor.

Title: Neuronal expression of H2-Db is sufficient for synaptic pruning and regulation of AMPA receptors

Authors: *H. LEE, B. K. BROTT, C. J. SHATZ;
Depts. Biology, Neurobiology, and Bio-X, James H. Clark Ctr., Stanford Univ., STANFORD, CA

Abstract: Major Histocompatibility Class I (MHCI) proteins, discovered in an unbiased screen for genes regulated by activity, are candidate key molecules for mediation of activity-dependent synapse remodeling. In mice lacking two MHCIs, H2-Kb and H2-Db (KbDb-/-), despite intact retinal activity and basal synaptic transmission, the developmentally regulated decrease in functional convergence of retinal ganglion cell inputs to LGN neurons fails, and eye-specific layers do not form. Neuronal expression of just H2-Db in KbDb-/- mice rescues both synapse pruning and eye specific segregation, despite a compromised immune system, underscoring a role for these molecules in neurons.

To study cellular mechanisms underlying the failure of pruning, whole cell recordings of EPSCs were made from LGN neurons in KbDb-/- vs WT mice. Prolonged AMPA currents at -70mV in KbDb-/- slices suggested the presence of Ca2+ permeable AMPA receptors. Consistently, decay time of EPSCs was significantly increased in KbDb-/- (WT: 13±4 ms; KbDb-/-: 55±15 ms, $p < 0.05$). To examine if there are changes in Ca2+ permeability, we analyzed subunit composition in AMPARs. Slightly increased GluA1 subunit protein levels but no changes in the GluA2 subunit are detected in KbDb-/- thalamus, suggesting an altered GluA1/2 ratio. To study the link between AMPAR subunit composition and H2-Db further, cortical neurons were studied in vitro. Using biotinylation and H2-Db/Kb-specific antibodies, H2-Db protein was detected on the cell

surface. Next, layer 2/3 pyramidal neurons were labeled by in-utero electroporation and then grown in vitro. Whole cell recordings from these neurons show that amplitude and frequency of mEPSCs (Vh -70 mV) are significantly increased in KbDb-/- (Amplitude:WT: 18.5 pA± 1.6; KbDb-/-: 23.7pA± 1.4, $p < 0.05$; Frequency: WT:1.9Hz± 0.9, n=10; KbDb-/-: 5.5 Hz ± 1.0, n=9, $p < 0.05$). GluA1 protein levels are also significantly increased ($p<0.03$) in KbDb-/- cortical neuronal cultures, with no significant changes in GluA2, yielding a higher GluA1/2 ratio. Thus, the subunit composition of AMPA receptors is altered in favor of Ca2+ permeability through AMPA receptors in KbDb-/-. These observations suggest that H2-Db regulates GluA1 levels in AMPARs, leading to altered Ca2+ permeability. The increase in Ca2+ influx through AMPARs in KbDb-/- could bias synaptic learning rules at retinogeniculate synapses away from LTD and towards LTP, thereby preventing synaptic weakening leading to synapse removal and pruning.

Title: Hippocalcin signaling in hippocampal LTD

Authors: *P. V. BELAN[1,2], A. DOVGAN[1], N. KONONENKO[1], V. CHERKAS[1], T. TSUGORKA[1], L. HAYNES[3], R. D. BURGOYNE[3];
[1]Bogomoletz Inst. Physiol, Kiev, Ukraine; [2]Key State Lab. of Mol. and Cell. Biol., Kiev, Ukraine; [3]Univercity of Liverpool, Liverpool, United Kingdom

Abstract: It has been previously shown that neuronal Ca2+ sensor protein, hippocalcin (HPCA), functions as a Ca2+ sensor in NMDAR-dependent LTD in the hippocampus. However, particular biophysical mechanisms of HPCA signaling during expression of LTD have not been studied yet. Here we show that simultaneous postsynaptic depolarization and low frequency presynaptic stimulation of cultured hippocampal neurons resulted in HPCA translocation to the plasma membrane associated with LTD of AMPAR-mediated excitatory postsynaptic currents. The

translocation was observed in 1-3 um sites on the plasma membrane located in both dendritic spines and shaft. HPCA was gradually (10-100 s) accumulated in the translocation sites integrating presynaptic neuronal activity. Translocated HPCA was being inserted into the plasma membrane for a prolonged period of time (decay constant 93±36 s) after termination of LTD expression protocol. This decay was significantly longer compared with a decay of HPCA translocation induced in the same set of sites after high frequency stimulation (6.2±3.0 s). Besides, sets of sites revealing translocation to low and high frequency presynaptic stimulation were not overlapped indicating that HPCA may decode different presynaptic inputs into specific spatio-temporal patterns of translocation in the plasma membrane of dendritic tree. Neither postsynaptic depolarization nor presynaptic stimulation alone did not produce HPCA translocation and only their association resulted in significant and substantial translocation. Calcium imaging in translocation sites demonstrated a moderate steady state increase of [Ca2+]i in a response to the postsynaptic depolarization and a fast transient responses to presynaptic stimulation. HPCA effectively filtered out these types of [Ca2+]i changes and translocated to the plasma membrane sites only in case when pre- and postsynaptic activity was properly associated in time. Thus, we conclude that biophysical properties of HPCA are perfectly suited to nonlinearly and associatively decode neuronal activity occurring during expression of LTD leading to HPCA insertion into the plasma membrane sites where it may initiate AMPAR endocytosis.

Title: Roles for presynaptic N- and P/Q-type calcium channels in plasticity of cortical afferents in the dorsolateral striatum

Authors: *D. A. KUPFERSCHMIDT, D. M. LOVINGER;
Synaptic Pharmacol., NIAAA / NIH, Rockville, MD

Abstract: The dorsal striatum is essential for the formation of habits and motor skills, and these forms of learning are hypothesized to involve plasticity at striatal synapses. Cortical inputs to the

dorsolateral striatum (DLS) exhibit various forms of plasticity that manifest as short- or long-term depression (STD, LTD) of glutamate release. Despite the presynaptic locus of expression of corticostriatal STD and LTD, their presynaptic mechanisms remain largely unexplored. We developed a novel approach to detecting presynaptic calcium (Ca2+) influx in cortical terminals in the DLS, and used it to probe the involvement of presynaptic Ca2+ in corticostriatal plasticity. Following Cre-dependent viral expression of the genetically encoded Ca2+ indicator GCaMP6 in motor cortex projection neurons of Emx1-Cre mice, we used fluorescence photometry to record, in slice, electrically evoked presynaptic Ca2+ transients (preCaTs) within the DLS. Tetrodotoxin-sensitive Na+ channels, cadmium-sensitive voltage-gated Ca2+ channels, and extracellular Ca2+ were required to evoke preCaTs. Application of the selective N- and P/Q-type Ca2+ channel blockers, w-conotoxin GVIA and w-agatoxin IVA, during preCaT recording revealed that N-type channels preferentially contribute to preCaTs in motor cortex projections to the DLS. Likewise, N-type channels appear to have a larger role in synaptic transmission evoked by stimulation of glutamatergic afferents in the DLS. Application of the GABA-B agonist, baclofen, and the mGluR2/3 agonist, LY379268, induced STD of both preCaTs and striatal field potentials. Studies are underway to assess the role of presynaptic Ca2+ influx in endocannabinoid- and serotonin-mediated corticostriatal LTD. These findings provide new insight into the presynaptic mechanisms of corticostriatal plasticity that may contribute to striatal-dependent learning.

Title: Nitric oxide in striatal synaptic plasticity

Authors: *I. RAFALOVICH, J. PLOTKIN, A. MELENDEZ, D. J. SURMEIER;
Physiol., Northwestern Univ., Chicago, IL

Abstract: Disruption in striatal synaptic plasticity contributes to many basal ganglia associated disorders including Parkinson’s and Huntington's disease. Nictric oxide (NO) signaling machinery is abundant in the striatum, however, its role in striatal synaptic transmission is unclear. Using whole-cell brain-slice electrophysiology we observed that NO signaling induced long-term depression (LTD) at cortico and thalamostriatal synapses. This effect was post-

synaptic, dependent on protein kinase G, and augmented by phosphodiesterase inhibition. In addition, NO signaling occluded the conventional, mGluR - dependent LTD through inhibition of L-type calcium currents. These results provide insight into the regulation of corticostriatal synaptic strength with implications for physiological control of motor function in health and disease.

Title: Convergence of synaptic pathophysiology in the hippocampus of the Syngap+/- and Fmr1-/y mice

Authors: *S. BARNES[1], A. D. JACKSON[1], E. M. OSTERWEIL[2], N. KOMIYAMA[1], S. G. N. GRANT[1], M. F. BEAR[2], P. C. KIND[1], D. J. A. WYLLIE[1];
[1]Ctr. of Integrative Physiol., Univ. of Edinburgh, Edinburgh, United Kingdom; [2]Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: Intellectual disabilities (IDs) and autism spectrum disorders (ASDs) are genetically heterogeneous disorders that display a high degree of co-occurrence. Despite their genetic heterogeneity, there is emerging evidence that there is convergence on common neuropathological axes, both in terms of the core cellular processes and the biochemical pathways being affected. One such axis is defined by metabotropic glutamate receptor (mGluR)-dependent protein synthesis, and modulators of this process prevent and/or reverse many of the phenotypes associated with mouse models of Fragile X Syndrome (FXS) and Tuberous Sclerosis. ERK-MAPK is a key regulator of mGluR-dependent protein synthesis and a recent screen of ID patients has revealed heterozygous *de novo* mutations in *SYNGAP1*, a negative regulator of the Ras/Erk pathway, in approximately 4% of individuals. We sought to determine

whether mice with heterozygous null mutations in *Syngap1* show similar core cellular deficits to those found in the mouse model of FXS.
One of the prominent phenotypes reported in the *Fmr1*$^{-/y}$ mouse is that a form of hippocampal long-term depression (LTD) mediated by the activation of Group 1 (Gp1) mGluRs is enhanced and independent of new protein synthesis. We examined mGluR-LTD at Schaffer collateral/commissural inputs to CA1 pyramidal neurones in hippocampal slices obtained from *Syngap*$^{+/–}$ mice. Extracellular field recordings reveal that acute application of the Gp1 mGluR agonist dihydroxyphenylglycine (DHPG; 50 µM) induces a form of mGluR-LTD that is of greater magnitude in *Syngap*$^{+/–}$ mice relative to wild-type (WT) littermate controls (57 ± 7 %, *Syngap*$^{+/–}$, n = 14 versus 75 ± 3 %, WT, n = 19). Furthermore mGluR-LTD in *Syngap*$^{+/–}$ mice is insensitive to protein synthesis inhibitors (unpaired t-test $P<0.05$, n = 15). In addition, we find basal levels of protein synthesis to be elevated in hippocampal slices from *Syngap*$^{+/–}$ mice relative to their WT counterparts (145 ± 15 %, *Syngap*$^{+/–}$ versus 100 ± 4 %, WT n = 12).The comparable neuropathophysiology we observe between *Syngap*$^{+/–}$ and *Fmr1*$^{-/y}$ mice suggests that SynGAP and FMRP may converge on similar biochemical pathways raising the intriguing possibility that therapeutic strategies used in the treatment of FXS may also be of benefit for individuals with ID caused by mutations in *SYNGAP1*.

Abstract: Long-term depression (LTD) reduces the functional strength of excitatory synapses through mechanisms that include the removal of AMPA glutamate receptors from the

postsynaptic membrane. LTD induction is also known to result in structural changes at excitatory synapses, including the shrinkage of dendritic spines. Synaptic adhesion molecules are thought to contribute to the development, function, and plasticity of neuronal synapses largely through their trans-synaptic adhesions. However, little is known about how synaptic adhesion molecules are altered during LTD. We report here that NGL-3 (netrin-G ligand-3), a postsynaptic adhesion molecule that trans-synaptically interacts with the LAR family of receptor tyrosine phosphatases and intracellularly with the postsynaptic scaffolding protein PSD-95, undergoes a proteolytic cleavage process. NGL-3 cleavage is induced by NMDA treatment in cultured neurons and low frequency stimulation in brain slices and requires the activities of NMDA glutamate receptors, matrix metalloproteinases (MMPs), and presenilin/gamma-secretase. These results suggest that NGL-3 is a novel substrate of MMPs and gamma-secretase and that NGL-3 cleavage may regulate synaptic adhesion during LTD.

Sch. of Med., Osaka, Japan

Abstract: Synapse function and plasticity depend on the morphology of dendritic spine. Dendritic filopodium is highly dynamic structure, known as a premature form of the dendritic spine. Here, we report that phldb2 (pleckstrin homology-like domain, family B, member 2), one binding partner for a well-known actin-cross-linking protein Filamin A, works as a positive

regulator of spine maturation. We generated Phldb2-knockout mice and found that a proportion of immature spines (filopodia and thin spines) increased in the hippocampus in vivo, which is consistent with our previous observations with Phldb2 knocked-down cultured hippocampal neurons. Next, we asked whether or not Phldb2 is involved in synaptic plasticity. We observed that NMDA-induced AMPA receptor endocytosis and low-frequency stimulation-induced long-term depression were blocked in hippocampal neurons of the Phldb2-knockout mice. Therefore, it is likely that Phldb2 plays an important role for the maturation of dendritic spines and for the synaptic plasticity.

Abstract: A central tenet of most theories of synaptic modification during cortical development is that correlated activity drives plasticity in synaptically-connected neurons. In contrast, using sensory-evoked activity patterns recorded from the developing mouse cortex in vivo, we uncovered a synaptic learning rule that relies solely on the presynaptic neuron. A burst of three

presynaptic spikes at a frequency of at least 50 Hz followed, within a restricted time window of 50-200 ms, by a single presynaptic spike induced robust long-term depression (LTD) at developing layer 4-to-layer 2/3 synapses. This presynaptic spike pattern-dependent LTD (p-LTD) could be induced by individual presynaptic layer 4 cells in paired recordings of synaptically connected neurons, required presynaptic NMDA receptors and calcineurin, as it was blocked by loading MK801 or FK506 into the presynaptic neuron via the patch pipette, and was expressed presynaptically as indicated by fluctuation analysis. Spike timing-dependent LTD (t-LTD) and p-LTD converge mechanistically on NMDA receptors, as they occluded each other, but in contrast to t-LTD, p-LTD did not require mGluRs, postsynaptic Ca2+-dependent processes, CB1 receptors or astroglial signalling. A form of p-LTD was also observed at horizontal synapses between L2/3 neurons. This spike pattern-dependent learning rule complements timing-based rules and is likely to play a role in the pruning of synaptic input during cortical development.

Title: Heterosynaptic plasticity of excitatory inputs to inhibitory neurons in rat visual cortex *In vitro*

Authors: *V. ILIN[1], M. ROSCHIN[1,2], M. CHISTYAKOVA[1], M. VOLGUSHEV[1];
[1]Psychology, Univ. of Connecticut, Storrs, CT; [2]Inst. of Higher Nervous Activity and Neurophysiol., Moscow, Russian Federation

Abstract: Long-term changes are typically studied at synapses that were activated during plasticity induction protocol - homosynaptic plasticity. However, Hebbian learning rules introduce a positive feedback on synaptic weight changes, making them prone to runaway dynamics. In our prior work we have described a form of plasticity in neocortical pyramidal neurons that can be induced by intracellular tetanization - bursts of postsynaptic action potentials, without presynaptic stimulation. This form of heterosynaptic plasticity (plasticity at synapses that were not active during the induction) can effectively prevent runaway dynamics of synaptic weights and neuronal firing.

Here we ask: (i) whether heterosynaptic plasticity can be induced by intracellular tetanization at excitatory inputs to inhibitory neurons in the neocortex, and (ii) whether heterosynaptic plasticity in inhibitory cells has different properties from those in excitatory neurons. We made whole-cell recordings from inhibitory neurons in slices from rat visual cortex. Excitatory postsynaptic potentials were evoked in the recorded cells by paired pulses applied to bipolar extracellular electrodes. Intracellular tetanization (3 trains of 10 bursts of 5 spikes at 100 Hz) induced long-term potentiation in 41 of 120 (34%) inputs to inhibitory neurons, long-term depression in 37 (31%) inputs, and did not change responses in 42 (35%) inputs. These plastic changes differed from those induced by intracellular tetanization in pyramidal neurons in the following respects. First, the direction of plastic changes in inhibitory neurons did not depend on initial paired-pulse ratio, as it did in pyramidal neurons. Second, the direction of plasticity in inhibitory neurons was correlated with the slope of EPSP: responses with steeper slopes had higher probability to be potentiated, while responses with slower slopes expressed depression more often. This correlation indicates possible distance-dependence of predispositions for potentiation and depression. Third, the magnitude of potentiation in inhibitory neurons (143+25%) was smaller than in excitatory neurons (171+56%, $p<0.001$). Similar to excitatory cells, long term plasticity in inhibitory neurons was associated with changes of release indices. EPSP amplitude changes were negatively correlated with changes of paired-pulse ratio, and positively correlated with changes of inversed coefficient of variation, indicating involvement of presynaptic mechanisms. Since presynaptic fibers were not activated during our induction protocol, presynaptic changes imply involvement of retrograde signaling.

University, Sch. of Sci. and Tech., Kwansei Gakuin Univ, S. N. Kudoh's Lab,, Sanda/ Hyogo, Japan

Abstract: Cultured rat hippocampal neuronal network on a multi electrode array (MEA) dish is a useful model for analyzing electrical network dynamics. Neurons autonomously form a complex network on a dish with 64 planar microelectrodes array. Autonomous electrical activity without evoking stimulus was recorded from the electrodes. The autonomous activity is generated by mutual interaction between neurons and it reflects internal states of neuronal network. It is plausible that the autonomous activity is influenced by energy intake. We elucidated the relationship between autonomous electrical activity and external glucose concentrations. The number of electrical spikes in autonomous activity increases depending on external glucose concentration. The number of spikes is the most at 15 mM glucose concentration and then decreased when the concentration was more than 20 mM. The glucose concentration for the most frequent activity was near the concentration in the culture medium, suggesting that the neurons were adapted to that concentration. In addition, the decrease of spikes at high glucose concentration was not influenced by the blockade of inhibitory synaptic inputs. These results suggest that autonomous activity in cultured neuronal networks depends on the amount of an external energy source.

Title: Heterosynaptic plasticity and synaptic competition

Authors: *J.-Y. CHEN[1], C. LEE[2], M. CHISTIAKOVA[2], M. VOLGUSHEV[2], M. BAZHENOV[1];

[1]Dept. of Cell Biol. and Neurosci., Univ. of California, Riverside, Riverside, CA; [2]Psychology, Univ. of Connecticut, Storrs, CT

Abstract: Spike timing dependent synaptic plasticity (STDP) is experimentally well-characterized form of plasticity that modifies synaptic weights depending on the relative timing of presynaptic input and postsynaptic spikes. This formal rule is broadly used in computational models of learning and developmental processes. However, STDP and other conventional Hebbian-type plasticity rules impose a positive feedback on synaptic changes, and are prone to produce runaway dynamics of synaptic weights and neuronal activity. Nevertheless, learning of complex associations for both declarative and procedural memories requires a broad distribution of synaptic weights. To achieve this and to keep system susceptible for new learning, stabilization mechanisms that prevent synapses from runaway potentiation or depression and associated over-excitability or complete silencing of neurons are necessary. In our prior work we described a form of heterosynaptic plasticity in vitro that can be induced by intracellular tetanization - a purely postsynaptic protocol without presynaptic stimulation. We implemented this form of heterosynaptic plasticity in computer model and demonstrated that it can serve as a normalizing mechanism and prevent runaway synaptic dynamics over a broad range of STDP rules. Here, we explored whether stabilizing effect of heterosynaptic plasticity still leaves room for synaptic competition. Synaptic inputs to a model neuron have been segregated into groups, which either expressed different degree of correlation between firing of presynaptic neurons, or fired at different rates. In the STDP-only model, synapses receiving highly correlated (or high firing rate) inputs were rapidly potentiated and their weights saturated at the maximal value. Synapses receiving weakly correlated (or low firing rate) inputs expressed little plasticity, and their distribution essentially did not change. In the model with both STDP and heterosynaptic plasticity, final synaptic weights of synapses from different groups formed compact and clearly separated distributions. In contrast to the STDP-only model, none of the synapses expressed runaway dynamics, but all synaptic weights remained within the operation range. We conclude that although heterosynaptic plasticity effectively counteracts runaway dynamics of synaptic weights, it does not preclude activity-dependent plasticity. Synapses from presynaptic neurons that fire together (or at higher rate) acquire higher weights than synapses from presynaptic neurons that exhibit low-correlated (or low rate) firing.

Title: Ripples enable replay-induced synaptic plasticity in the hippocampus

Authors: *J. SADOWSKI, J. R. MELLOR, M. W. JONES;
Physiol. and Pharmacol., Univ. of Bristol, Bristol, United Kingdom

Abstract: Mounting evidence suggests that hippocampal sharp wave/ripple oscillations play an important role in memory consolidation. Ripples occur primarily during off-line quiescent states and are preferentially associated with replay of sequential activity associated with recent behavioural episodes. It is not known how ripple-associated replay facilitates memory consolidation, but synaptic plasticity is likely to play a pivotal role. Here we test whether replay activity recorded from hippocampal place cells in vivo is capable of inducing synaptic plasticity in hippocampal slices.

Tetrodes were used to record multiple single unit and local field potential (LFP) simultaneously from CA3 and CA1 of the dorsal hippocampus during alternating periods of track running and quiescence in 3 adult male Wistar rats (10-12 weeks old); place field, cross-correlation and spectral analyses were used to examine experience-dependent changes in CA3-CA1 network activity. Spike trains from selected CA3 and CA1 pyramidal neurons were then reiterated in dorsal hippocampal slices prepared from age-, sex- and strain-matched rats using whole-cell patch clamp recordings from CA1 pyramidal cells and synaptic responses elicited by stimulation of Schaffer Collateral (SC) axons. In addition to action potential firing, SC stimulation was used to simulate bursts of subthreshold synaptic input received by CA1 pyramidal cells during ripples (Maier, Tejero-Cantero et al. 2011). Replay activity patterns from CA3-CA1 place cell pairs coactivated during exploration of a novel environment are capable of inducing long-term potentiation. However, LTP is only expressed if replay patterns are delivered concurrently with simulated sub-threshold ripple oscillations.

This dependence of LTP on ripple-associated synaptic input suggests that the combination of sequential action potential firing coupled with ripple oscillations during quiescent behavioural states plays an enabling role in optimising the induction of synaptic plasticity likely to underlie memory consolidation.

Title: Neuromodulators-mediated consolidation of STDP eligibility traces

Authors: *K. HE, A. KIRKWOOD;
Mind/Brain Inst., The Johns Hopkins Univ., Baltimore, MD

Abstract: Neuromodulators are thought to serve as reward signals in reinforcement-based and reward-based learning, including perceptual learning. A significant challenge for understanding this type of learning is the "credit assignment" or "distal reward problem": how synapses that were active before the arrival of the reward are modified. Theoretical studies postulate that the synaptic activity underlying learning 'tags' the synapses with a short-lived 'eligibility trace', by which the delayed reward identify the target synapses. Here we present experimental evidence to support this hypothesis. We found in the primary visual cortex (V1) that the spike-timing stimulation (correlated firing of pre- and postsynaptic neurons) can generate synapse-specific 'eligibility traces'. Stimulation of serotonergic and adrenergic receptors shortly afterwards consolidates these traces into either LTP or LTD depending on the STDP patterns as well as the modulators. We propose this neuromodulator-mediated consolidation of traces induced by STDP as a candidate cellular mechanism for reward-based perceptual learning.

Title: Spatiotemporal input dependent plasticity in cortical pyramidal cell dendrites

Authors: M. MACAK[1], T. BRANCO[2], *M. HAUSSER[1];
[1]UCL, London, United Kingdom; [2]MRC Lab. for Mol. Biol., Cambridge, United Kingdom

Abstract: Dendrites of pyramidal cells are known to be sensitive to distinct spatiotemporal patterns of inputs, which could be important for computations performed in sensory cortices. This sensitivity depends on the gradient of input impedance along dendritic branches and on NMDA receptor activation (Branco, Clark, & Häusser, Science 2010), whereby different temporal sequences recruit different amounts of NMDAR conductance. Given the well-known dependence of multiple forms of plasticity on NMDA receptors it is possible that different temporal sequences of synaptic inputs could result in differential plasticity. Such mechanism could, in theory, increase the computational power of dendrites and provide a biophysical basis for long-term storage of specific spatiotemporal input patterns. Here we investigated the possibility of sequence-dependent plasticity by combining 2-photon MNI-glutamate uncaging and whole-cell electrophysiological recordings from layer 5 pyramidal cells in acute slices of rat somatosensory cortex. Using high-frequency spike-timing dependent plasticity protocols (STDP), we first demonstrate that sequential synaptic activation along single dendritic branches can reliably result in timing-dependent long-term potentiation, in both apical (mean LTP = 208%, N=5) and basal dendrites (mean LTP = 185%, N=4). We are currently exploring the sensitivity of these plasticity mechanisms to different temporal sequences during STDP induction.

Title: Reoccurring spatiotemporal optogentic stimulation pattern induces plasticity in a cortical neuron

Authors: *V. LERNER[1], S. ZIBMAN[1], H. SOMPOLINSKY[1,2], M. LONDON[1], Y. YAROM[1];
[1]The Edmond & Lily Safra Ctr. for Brain Sci., [2]Racah Inst. of Physics, Hebrew Univ. of Jerusalem, Jerusalem, Israel

Abstract: How does the brain identify and produce patterns of information required to process sensory information and to create motor commands? One possibility proposed by theoretical studies is that individual neurons can learn to respond to specific reoccurring spatiotemporal patterns of synaptic inputs that repeat in the presence of background activity. Several models have been suggested to explain both unsupervised (Masquelier et. al. 2008) and supervised (Gutig & Sompolinsky 2006) learning. All these models rely on synaptic plasticity to strengthen synapses associated with the desired input and weakening the others but there is yet no experimental evidence to determine the validity of the theoretical works.
We combine whole cell recordings in vitro with optogenetics and multispot illumination to address this question. We use Cop4 Thy-1 transgenic mice expressing Channelrhodopsin 2 (ChR2) sparsely in layer V somatosensory cortex. We record intracellularly from a cell not expressing ChR2. We create a grid of 100 illumination spots surrounding the neuron and map their individual postsynaptic response to light activation. We then generate spatiotemporal light patterns consisting of multi-site activation (1-10 spots) separated by 20-30 ms. The recorded cell is "trained" by a repetitive presentation of a specific spatiotemporal pattern embedded within a random sequence, as suggested by (Masquelier et. al. 2008). This type of massive activation results in profound plastic changes in the individual synaptic responses, which might lead to pattern recognition. This research is supprted by the FP7-ICT (Realnet) grant.

Title: Natural firing patterns reduce sensitivity of synaptic plasticity to spike-timing

Authors: *S. OSTOJIC[1], M. GRAUPNER[2];
[1]Ecole Normale Superieure, Paris, France; [2]New York Univ., New York, NY

Abstract: Synaptic plasticity is sensitive to both the rate and the timing of pre- and postsynaptic spikes. In experimental protocols used to induce plasticity, the imposed spike trains are regular and the relative timing between every pre- and postsynaptic spike is fixed. This is at odds with natural firing patterns observed in the cortex of intact animals, where cells fire irregularly and the timing between pre- and post-synaptic spikes varies.
To investigate synaptic changes elicited by in vivo-like irregularly firing neurons at different rates and realistic correlations between pre- and post-synaptic spikes, we use numerical simulations and mathematical analysis of synaptic plasticity models. We concentrate on a spike-timing model based on spike-pairs (Gerstner et al. 1996), spike-timing model based on spike-triplets (Pfister and Gerstner 2006), and further consider a calcium-based model (Graupner and Brunel 2012). The voltage-based model (Clopath et al. 2010) and the spike-triplet model (Pfister and Gerstner 2006) behave equivalently and we consider only the latter. To allow for comparison, all models are fitted to plasticity results obtained in vitro (Sjostrom et al. 2001).
We show that stimulation protocols with regular spikes and fixed relative timings overestimate the influence of spike-timing on synaptic plasticity. Using a simple modification of regular spike-pair protocols, we allow for neurons to fire irregularly. Such irregular spike-pairs reduce the amplitude of potentiation and depression obtained by varying the time difference between pre- and postsynaptic spikes. This protocol allows us to quantify the relative effects of firing rate and timing in natural firing patterns, and to predict changes induced by an arbitrary correlation function between pre- and post-synaptic spikes. We show that spike correlations considerably change synaptic plasticity at low firing rates in all models; as firing rates increase the influence of correlations remains strong in the spike-pair model, but diminishes in the triplet model and becomes negligible in the calcium-base model. Our findings yield predictions for novel experiments and help bridge the gap between existing results on synaptic plasticity and plasticity occurring under natural conditions.

Title: Role of experience in plasticity outcomes of spatially separate synaptic pathways onto individual neurons in mouse visual cortex

Authors: *O. M. FITCH[1,2], M. J. FRIEDLANDER[1];
[1]Virginia Tech. Carilion Res. Inst., Roanoke, VA; [2]Neurosci., Baylor Col. of Med., Houston, TX

Abstract: In the neocortex, individual cells of like type can undergo heterogeneous plasticity responses from depression (LTD) to potentiation (LTP), or no change (NC) in response to a common fixed time delay synaptic conditioning protocol. However it is not known whether all synapses onto a common cell have the same plasticity outcome. Nor is it known what role visual experience plays in shaping the distribution of differential plasticity outcomes. Thus, we evaluated the synaptic plasticity responses of separable sets of synaptic inputs onto common postsynaptic neurons in primary visual cortex in response to simultaneous stimulation of distinct sets of afferents in acute brain slices from visually intact and in binocularly deprived mice. Animals were binocularly deprived from before the natural time of eye-opening. The two stimulation sites were isolated by occlusion testing followed by alternative activation of each pathway to evoke a postsynaptic potential (PSP) every 10 seconds in an interleaved fashion. After a stable ten minute baseline period, the activation of both pathways was simultaneously paired with direct postsynaptic activation that preceded the synaptic stimulation by 10 milliseconds resulting in 4-7 postsynaptic spikes at 0.1 Hz over a 10 min period followed by reversion to the interleaved stimulation protocol for an additional 30 minutes. The ratio of the average amplitude of the evoked PSP post/pre conditioning was calculated for each pathway taking the 5 minutes average peak amplitude over 25-30 minutes post-conditioning compared to 5 minutes just before or pre-conditioning. Our results from 57 pathways inputs validate in the mouse cortex our previous findings from other species demonstrating heterogeneous plasticity outcomes ranging from LTD to LTP for individual cells with a mean post/pre ratio of 0.87 +/- 0.32sd for the grouped results. Preliminary data comparing 30 pathways in the binocularly deprived animals also resulted in a similar range of individual plasticity outcomes with an average post/pre ratio of 0.88+/-0.40sd for the grouped results that was not significantly different from visually intact animals (p=0.95 t-test). When the plasticity outcomes of the separate pathways were compared to determine whether each set of synapses onto a common cell had similar plasticity behavior, we found that they were independent both in the visually intact animals with a $\chi 2$ of 1.6, 5 df, p=0.9 and in binocularly deprived animals $\chi 2$ of 5.6, 5 df, p=0.35. Thus, synaptic plasticity outcome variability is a local synaptic phenomenon vs. a whole cell property and appears to be intrinsic vs. modifiable by visual experience.

Title: Twenty four hour sweetened high fat food treatment increases excitatory synapses onto vta dopamine neuron in mice

Authors: *S. LIU, S. BORGLAND;
Dept. of Physiol. and Pharmacol., Univ. of Calgary, Calgary, AB, Canada

Abstract: Over-consumption of palatable food can lead to obesity. Dopamine neurons of the ventral tegmental area (VTA) are part of a critical circuit for reward seeking and hedonic feeding. Previously, we demonstrated that insulin can induce long-term depression (LTD) of VTA dopamine neurons via endocannabinoid-mediated presynaptic mechanism and this LTD can be occluded by a sweetened high-fat meal (SHF). In the present study, mice had 24 hour access to either SHF or regular food (RF). While caloric consumption was similar between RF and SHF mice, plasma insulin was significantly increased in mice fed SHF. Significant differences in the efficacy of excitatory synaptic transmission onto VTA dopamine neurons were observed between RF and SHF fed mice. Similar to 1h access to SHF, 24 hours of SHF increased endocannabinoid tone at excitatory synapses onto dopamine neurons. However, the co-efficiency variance of mEPSC amplitudes was significantly less in these mice, suggesting possible increased excitatory synapse formation onto dopamine neurons. These data suggest that synaptic depression induced by increased endocannabinoid tone may be offset by increased synapse formation. Consistent with this, there was no significant difference in mEPSC frequency and the latency to maximal spike-timing dependent long term potentiation (STDP) was significantly less in mice fed SHF. Taken together, these data suggest that 24 h access SHF results in synaptic plasticity at excitatory synapses in the VTA.

Title: Cultured cortical neurons can detect a higher-probability hidden signal source with multi-electrode stimulation

Authors: *T. ISOMURA, K. KOTANI, Y. JIMBO;
Dept. of Human and Engineered Envir. Studies, Grad. Sch. of Frontier Sci., The Univ. of Tokyo, Chiba, Japan

Abstract: Computational studies demonstrate that simulated neural networks can perform Principal component analysis (PCA); however, few studies have examined the neural basis of PCA-like learning. Here, we demonstrate that cultured cortical neurons can detect a higher-probability hidden signal source with multiple input signals. Approximately 500,000 dissociated cells obtained from the 19-day embryonic rat cortex were seeded on microelectrode array (MEA) dishes and cultivated for more than 3 weeks. We electrically stimulated the neurons with 256-s pulse trains that were applied at 1-s intervals. The stimulation was applied through 32 electrodes and was repeated for 100 cycles. These trains were constructed using two independent binary signal sources, u1(t) and u2(t). The values for half of the stimulus trains were randomly selected at each time period by u1(t) with a probability of 3/4, or by u2(t) with a probability of 1/4. The values for the remaining stimulus trains were randomly selected by u1(t) with a probability of 1/4, or u2(t) with a probability of 3/4. Neural responses evoked with the input trains were recorded with the 64-electrode MEA. Finally, we calculated the probability of the number of evoked spikes P(r). We observed a change in Kullback-Leibler divergence (KLD) between P(r|(u1,u2)=(1,0)) and P(r|(u1,u2)=(0,1)) as well as mutual information (MI) between P(r) and P(u1), or between P(r) and P(u2). For some electrodes, KLD increased (Fig.1) and one of the MIs with two hidden signal sources decreased after the training period, whereas KLD and MIs did not change significantly in the presence of 20 μM 2-Amino-5-phosphonopentanoic acid (APV) or without the stimulation. These results suggest that continuous stimulation induced synaptic plasticity in cultured neuronal networks, and that neurons located near some electrodes preferred to respond to a side of the hidden signal sources rather than respond to the input trains. Therefore, these results support the hypothesis that cortical neurons can detect the highest-probability or largest hidden signal source of input signals.

Title: Learning probabilistic inference in general graphical models with networks of spiking neurons

Authors: *D. PECEVSKI, W. MAASS;
Graz Univ. of Technol., Graz, Austria

Abstract: Many behavioral data as well as recent data in neuroscience [Berkes et al. 2011] suggest that the brain stores knowledge in form of probability distributions, which are then used to make inferences about the world based on observed facts. But it is still largely unknown how plasticity processes on a synaptic and neuronal level in the brain enable learning of knowledge in form of probability distributions. Recent theoretical results [Buesing et al., 2011, Pecevski et al., 2011] showed a novel way how a network of stochastic spiking neurons can "embody" a probability distribution as a distribution of network states, and perform probabilistic inference for it via Markov chain Monte Carlo sampling. Building on these results, we show here that a STDP-like synaptic plasticity mechanism together with plasticity of the intrinsic neuron excitabilities derived from basic theoretical principles, enable learning of a probability distribution in such networks of spiking neurons from input data streams. The approach assumes that there is prior knowledge about the existing independencies between the random variables in the probability distribution in the form of a graphical model structure. The neural networks are composed of interconnected winner-take-all network motifs with a connectivity that reflects the independencies in the graphical model and exploits these independencies to reduce the complexity of learning. The developed neural models are general in a sense that they can be applied for learning any probability distribution over discrete variables represented by any graphical model structure. We demonstrate the viability of the approach through computer simulations, where we train networks of spiking neurons to learn probabilistic models for two perceptual phenomena: perceptual explaining away and localization bias in multisensory integration. Altogether the results elucidate a novel integrated view of the functional role of synaptic plasticity, intrinsic plasticity and winner-take-all network motifs of spiking neurons: to support accumulation of knowledge in the probability distribution of network states.

Title: Neurogranin modulates the threshold for inducing LTP in spike-timing-dependent plasticity

Authors: *H. HWANG, K. J. JONES, W. XU;
Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: Neurogranin (Ng) is a small neuron-specific protein, and primarily expressed in the postsynaptic compartments of projection neurons in hippocampus. Ng has been shown to interact with calmodulin (CaM) in vivo under low calcium conditions, and its binding to CaM reduces the calcium binding affinity of CaM. We found that Ng levels in hippocampus can be rapidly upregulated in response to novel context exposure and adrenergic stimulation. This upregulation can also be recapitulated in the neuronal culture system by elevated excitatory drive. Considering the role of Ng in binding CaM, such activity-dependent regulation of Ng levels may alter the dynamics of Ca2+/CaM complex formation and rises in the free calcium levels upon the entry of calcium ions. Thus, changes in Ng levels can critically influence Ca2+- or Ca2+/CaM-dependent neuronal processes such as synaptic plasticity.
Here we examined the role of Ng in inducing long-term potentiation (LTP) with a spike-timing-dependent plasticity (STDP) protocol in acute hippocampal slices. Ng levels were manipulated in mouse hippocampal CA1 neurons in vivo by stereotaxically injecting lentivirus that either overexpresses Ng fused to eGFP, or knocks down endogenous Ng with shRNA specifically targeting Ng mRNAs. STDP was induced by pairings of the Schaeffer collaterals stimulation with postsynaptic neuron bursting at various positive time intervals, based on a previously reported protocol (PNAS, 108, 2011, 8450-8455). Knockdown of endogenous Ng abolished spike-timing-dependent LTP (t-LTP) at a time interval that uninfected control neurons exhibited reliable, robust potentiation. Whereas overexpression of Ng significantly enhanced the magnitude of t-LTP at a time interval that uninfected neurons exhibited only mild potentiation. Taken together, our results demonstrate that Ng levels play a crucial role in setting the threshold/magnitude of LTP in STDP.

Title: The roles of individual Ca^{2+} sources in plasticity under different synaptic conditioning patterns in visual cortex

Authors: *D. KALIKULOV, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: We compared the contributions of NMDARs, RyRs, IP_3Rs, and mGluRs to induction of synaptic plasticity in visual cortex pyramidal neurons in response to two different conditioning paradigms. One used low frequency stimulation (LFS - 0.1 Hz) of afferents while the other employed pairing of presynaptic activity induced by stimulation of afferents 10 ms after postsynaptic spiking induced by intracellular current injection in young (P6-P12) guinea pigs. LFS resulted in a net LTD (-13±2%; n=10) while individual cells underwent LTD or no change (NC). When LFS was applied with inhibition of NMDA receptors (bath applied D-AP5 - DL-2-Amino-5-phosphonopentanoic acid) prevented induction of LTD (50 µM d-AP5,+0.3±3%, n=14), while LFS applied with inhibition of mGluRs or IP_3Rs with bath applied MPEP (6-Methyl-2-(phenylethynyl)pyridine - 10 µM, -14+5%, n=9) or xestospongin C (1.0µM, -17+6%, n=11) respectively, did not alter the likelihood or magnitude of LTD. However, when LFS was applied with inhibition of RyRs, (200 µM ryanodine) the plasticity outcome shifted to a net long term potentiation (LTP) (+27±14%, n=16). Application of the pairing protocol resulted in a range of plasticity outcomes (LTP, LTD or NC), with an overall net LTP (+9±5%, n=30) while individual cells underwent LTD, NC or LTP. When pairing was applied with selective inhibition of each of the individual calcium sources, there were significant changes in the plasticity outcomes ($p \leq 0.05$; t-test) compared to the plasticity outcomes in response to pairing under control conditions. A net LTD occurred in the presence of inhibitors of NMDARs (50 µM d-AP5, -36±6%, n=20), or in the presence of inhibition of RyRs (200µM ryanodine, -31±6%, n=20). Conversely, a net LTP occurred in the presence of inhibitors of mGluRs (10 µM MPEP, +31±8%,n=27) or IP_3Rs (1.0µM xestospongin C, +31±9%, n=25). Evaluation of the plasticity outcome distributions across individual cells showed that inhibition of NMDARs or RyRs, resulted in LTD or NC, while inhibition of mGluRs or IP_3Rs resulted in NC or LTP. These results suggest that NMDAR activation is necessary for LFS stimulation induced LTD while

mGluR and IP_3R activation are not, and equivalent pairing of pre- and postsynaptic activity can access relatively different contributions of the various postsynaptic calcium signaling pathways in different neurons of like type under otherwise identical conditions. These differences may be due to intrinsic variability in the expression and/or compartmentalization of these calcium sources and/or the state or past experience of the individual cells/synapses.

Title: Characterizing topology-dependent network plasticity induced by electrical stimulation in silico

Authors: *R. NI, D. B. SINHA, N. M. LEDBETTER, D. L. BARBOUR;
Biomed. Engin., Washington Univ. in St. Louis, Saint Louis, MO

Abstract: Activity-dependent electrical stimulation can induce cortical reorganization in vivo by activating brain areas using stimulation derived from the statistics of neural or muscular activity. Regular failures of network-level reorganization, however, have been observed in experiments applying such stimulation protocols. These procedures were designed based upon the nature of monosynaptic Hebbian plasticity, but induced reorganization is likely to involve polysynaptic circuits. Unfortunately, the network manifestation of plasticity across multiple synapses is poorly understood. We hypothesize that the regular failures in stimulation-induced reorganization may be attributable to variations in network topology. In this study, we explored and characterized the influence of local neural circuit topology on the effectiveness of activity-dependent electrical stimulation in modulating synaptic strength. We simulated small-scale neural networks possessing feedforward and recurrent topologies, as well as the same small networks embedded within larger networks. Excitatory synapses were modulated by an unbounded but weight-dependent spiking-timing-dependent plasticity (STDP) rule. We used one type of activity-dependent electrical stimulation, spike-triggered stimulation (STS), to activate single neurons or groups of neurons based upon the ongoing activity of a reference neuron. The results demonstrate that STS-induced competition between the conditioned input and network synaptic

inputs yielded a new steady-state synaptic strength distribution that emerged during stimulation. Under some experimental conditions, STS elevated mean network firing rate and increased the mutual information between conditioned neurons and the unconditioned neurons. Stimulating a group of neurons rather than individual neurons revealed a wider range of information rerouting. STS effects for paired neurons with direct connections were generally large and could persist following the stimulation period in both small and larger neural networks. For paired neurons without direct connections, the effects of STS in small local circuits rapidly washed out after stimulation ended but were somewhat persistent in larger scale networks. This study provides insights into the understanding of the impact of local circuit topologies on activity-dependent stimulation, as well as polysynaptic plasticity, and will ultimately facilitate the effective manipulation of brain networks with activity-dependent stimulation.

Title: A modular attractor memory network with spike-based, probabilistic learning

Authors: P. J. TULLY[1,2,3], M. H. HENNIG[3], *A. B. LANSNER[4,1,2];
[1]Dept. of Computat. Biol., Royal Inst. of Technol. (KTH), Stockholm, Sweden; [2]Stockholm Brain Inst., Karolinska Institutet, Stockholm, Sweden; [3]Inst. for Adaptive and Neural Computation, Univ. of Edinburgh, Edinburgh, United Kingdom; [4]Numerical Analysis & Computer Sci., Stockholm, Sweden

Abstract: A rich set of computations emerges from the dynamics of networks of recurrently connected neurons. The attractor-memory paradigm provides a powerful yet simple approach to understanding how these dynamics could enable many aspects of cortical function [1], but this abstract mapping often occurs at the expense of biological plausibility. In these models, each memory is stored in a distributed fashion represented by increased firing in pools of excitatory neurons. Excitatory activity is locally modulated by inhibitory neurons representing lateral inhibition causing winner-take-all dynamics. Detailed network models of this type have previously been shown to exhibit switching between non-coding ground state and low-rate memory state activations displaying gamma oscillations [2], however it is unclear how such properties could be shaped by on-line Hebbian plasticity. Assuming a probabilistic framework in which local neuron populations discretely encode uncertainty about an attribute in the external world (e.g. a column in visual cortex tuned to a specific edge orientation), we seek to bridge this gap by modeling inter-module synapses using the Bayesian Confidence Propagation Neural Network (BCPNN) plasticity rule [3].
We use a spike-based version of BCPNN in which synaptic weights are statistically inferred by estimating the posterior likelihood of activation for the postsynaptic cell upon presentation of evidence in the form of presynaptic activity patterns. Probabilities are estimated on-line using local exponentially weighted moving averages, with time scales that are biologically motivated by the cascade of events involved in the induction and maintenance of long-term plasticity. Modulating the kinetics of these traces is shown to shape the width of the STDP kernel, which in turn allows attractors to be learned forwards or backwards through time. Stable learning is confirmed by a unimodal stationary weight distribution. Inference additionally requires modification of a distinct neuronal component, which we interpret as a correlate of intrinsic excitability. Incorporation of the learning rule allows for continuous real-time learning in the spiking attractor network.

Title: Plasticity of excitatory-inhibitory balance in the auditory cortex

Authors: *J. A. D'AMOUR, R. C. FROEMKE;
Mol. Neurosci., New York University, Sch. of Med., New York, NY

Abstract: In mature neuronal networks, excitatory and inhibitory responses are correlated, such that inputs that evoke large excitatory responses tend to evoke large inhibitory responses, and small excitatory responses are usually accompanied by small inhibitory responses, i.e., excitation and inhibition are balanced. While it is known that excitatory synapses are modified in an activity dependent manner, it remains unclear how inhibitory responses are modified following excitatory plasticity to restore balance. We have previously examined this phenomenon in vivo in adult (Froemke et al., Nature 2007) and developing rat auditory cortex (Dorrn et al., Nature 2010). Here we look at the synaptic mechanisms of excitatory-inhibitory balancing in young and adult mouse auditory cortex in brain slices, in order to examine this process in higher resolution. We made whole-cell recordings from layer 5 neurons in slices of mouse auditory cortex (postnatal day 12-24). First, we recorded from pyramidal cells and evoked excitatory or inhibitory responses with focal extracellular stimulation using an array of 4-8 stimulation electrodes to activate several point sources of excitatory and inhibitory inputs. After monitoring baseline responses, extracellular stimulation of one input channel was repetitively paired with a single postsynaptic spike for several minutes to induce spike-timing-dependent plasticity (STDP), and synaptic strengths of the entire population of 4-8 channels monitored thereafter. For excitatory inputs, pre-before-post pairing at short timing intervals (< 15 msec) induced long-term potentiation (LTP), while post-before-pre pairing induced long-term depression (LTD), as expected. These modifications were blocked by the NMDA receptor antagonist APV. Inhibitory STDP, however, showed a different learning rule from that of excitatory synapses, where-in both very short positive and negative pairings potentiated inhibitory responses, as predicted from a recent theoretical study (Vogels et al., Science 2011).
Modifications were also observed to unpaired inputs. We measured the effect of these homosynaptic and heterosynaptic changes by measuring the linear correlation between excitation and inhibition across the different input channels. When correlation was initially moderate to high ($r>0.4$), synaptic modifications had little positive effect on the post-pairing correlation. However, in 3/3 cases, when correlation began low (~0.3 or less), spike pairing at one input led to changes that collectively improved the overall correlation. We are now assessing the cellular mechanisms by which heterosynaptic modifications are induced.

Title: Feedforward and feedback inhibition differentially control the spike output patterns of CA1 pyramidal neuron

Authors: H. JANG, *J. KWAG;
Dept. of Brain and Cognitive Engin., Korea Univ., Seoul, Korea, Republic of

Abstract: Hippocampal pyramidal neuronal spike output patterns contain spike rate and temporal codes that are important in hippocampal spatial information processing. However, how the interneuronal network supports the generation of the two distinctive types of neural codes is yet unclear. Here, we investigated how the feedforward (FF) and feedback (FB) inhibitory network differentially modulate the spike output patterns of CA1 pyramidal cell (PC) by studying the input-output relation in a hippocampal network model.
The hippocampal network model consisted of a conductance-based CA1 PC receiving an afferent excitatory input from a CA3 PC. FF inhibition to CA1 PC was activated by the CA3 PC whereas FB inhibition to CA1 PC was activated by the recurrent inhibition activated by the CA1 PC. Input-output relation was quantified by analyzing the output frequency of a CA1 PC in response to the activation of CA3 PC at 2-100 Hz in each of the excitatory, FF and FB inhibitory network. In excitatory network, increasing the input frequency linearly increased the output frequency of CA1 PC (regression slope, a= 0.288). In the FB network, input-out relation also linearly increased, but the relation down-shifted (a = 0.200). In FF network, however, regardless of the input frequency, the output frequency was kept almost constant in the theta-frequency range (4-10 Hz, a = 0.0350). Temporal dynamics of the spike output was quantified by analyzing the inter-spike interval (ISI) and its coefficient of variation (CV). ISI of excitatory network and FB network showed small variation (CV=0.319 and 0.2284, respectively). Especially, FB inhibitory network showed a near constant ISI, suggesting that FB inhibitory network promotes synchronization of spike output patterns. However, FF inhibitory network showed comparably variable ISI with the greatest CV among the three network conditions (CV = 0.407).
Here we demonstrate that FF and FB inhibitory network differentially control spike output patterns of CA1 PC. FB inhibitory network may support synchronization of spike outputs promoting rate coding whereas FF inhibitory network may contribute to temporal coding in the theta-frequency range, suggesting that different inhibitory connections may have different functions in hippocampal information processing.

Title: Multichannel recordings in the medial prefrontal cortex during carbachol and group I metabotropic glutamate receptor activation

Authors: *M. POLLARD, H. SHABAN;
Janssen Pharmaceutica NV, Beerse, Belgium

Abstract: Neural plasticity deficits that involve group I metabotropic glutamate receptors (mGluRs) relate to cognitive decline in Fragile X Syndrome. Also, boosting of NMDA receptor-mediated currents by mGluR subtype 5 is relevant in the hypoglutamatergic hypothesis for schizophrenia. The advent of positive allosteric modulators (PAMs) that enhance receptor-mediated activation, while avoiding alterations in endognenous neurotransmission has led to studies that report mGluR5 PAMs as beneficial in rodents during cognitive tasks. We are interested in understanding the neuronal circuit dynamics responsible for group I mGluR-mediated effects in the medial prefrontal cortex, an area important in cognitive control. Moreover, we will determine the interplay with the arousal agent, carbachol (CCH) as an assessment for therapeutic potential during behavioral states. Multichannel extracellular recordings were performed in acute coronal slices of rat brain placed in a biochip (8x8 array; 40 μm electrodes; 200 μm spacing). Control consisted of Ringer's solution and drugs were perfused for 5 min prior to recordings for 1 min at 21°C. Spontaneous IPSCs were recorded separately in layer V principal cells at -70 mV with a high chloride internal solution. Action potential and IPSCs are presented as percent changes of the mean ± SE with respect to control levels and $p < 0.05$ with Student's t test. Results show that CCH (20 μM) or the group I mGluR agonist, DHPG (100 μM) caused an increase spread of spiking activity (11.45 ± 0.04%; 9.17 ± 0.01%; n = 80; $p < 0.05$, respectively). Either CCH or DHPG caused increases in IPSCs, which were not significant. The mGluR5 PAM, VU-29 (1 μM) caused no effect on its own though the mGluR5 antagonist, MTEP (10 μM) resulted in increased spiking activity (23.77 ± 0.02%; n = 20; $p < 0.05$) indicating that mGluR5-mediated basal transmission was present but constrained. Interestingly, no changes in IPSCs were observed following MTEP, however, VU-29 caused a

large enhancement (259.41 ± 104.52%; n = 17; $p < 0.05$) of CCH-evoked IPSCs. When combining CCH (14.11 ± 0.11%) with VU-29 or MTEP, spiking rate decreased (7.48 ± 0.11%) or increased respectively (84.10 ± 0.30%; n = 20; $p < 0.05$). In contrast, combinations with DHPG (55.15 ± 0.12%) resulted in enhanced spread of activity for both VU-29 (64.00 ± 0.12%) and MTEP (90.61 ± 0.15%; n = 30; $p < 0.05$) without affecting spike rate. These data implicate a role for mGluR5-mediated feedforward inhibition in maintaining signal to noise ratios for relevant inputs during attention. It also emphasizes the influence of neuronal circuits in dictating response outputs important for assessing the effects of drug candidates.

Title: Neural circuit that computes direction selectivity in mouse retina

Authors: J. S. KIM[1], M. GREENE[1], A. ZLATESKI[1], M. RICHARDSON[1], M. BALKAM[1], M. PURCARO[1], *H. SEUNG[1], M. HELMSTAEDTER[2], K. BRIGGMAN[2], W. DENK[2]; [1]Brain & Cog Sci. Dept., MIT, CAMBRIDGE, MA; [2]Max Planck Inst. of Neurobio., Munich, Germany

Abstract: The J retinal ganglion cell (J-RGC) is a genetically identified ganglion cell type in mouse retina that shows direction selectivity. We studied subcellular and intercellular organization of the direction selective circuit involving the J-RGC. With help of EyeWire, a community of citizen neuroscientists, we reconstructed a few J-RGCs and their synaptic inputs from serial electron microscopic images. We found that type 3/4 bipolar cells and starburst amacrine cells synapse primarily onto the dendrites of J-RGC proximal to its soma, while inputs from type 1/2 bipolar cells are dominate on the distal J-RGC dendrites. Such wiring specificity is a consequence of subtle differences in the stratification of proximal and distal dendrites of J-RGCs. Based on the observation, we introduce an excitory/inhibitory circuit model for direction selectivity. The study suggests that intercellular wiring wiring specificity is governed by subcellualar structures of different types of cells and that the visual function of J-RGC is intimately related to the morphology of itself as well as its circuit structure.

Title: Local differences in axonal action potential conduction velocity

Authors: *D. J. BAKKUM[1], U. FREY[2], M. RADIVOJEVIC[1], J. MUELLER[1], M. FISCELLA[1], H. TAKAHASHI[3], A. HIERLEMANN[1];

Abstract: Accumulating evidence shows that neocortical axons may play more important roles in neural computation than generally considered, namely, by regulating action potential propagation. For example, previous work demonstrated that neurons could temporally tune the propagation of their action potentials between two sites (Bakkum et al. 2008): Activity-dependent plasticity occurred as networks adapted to patterns of electrical stimulation and was regulated on the minutes to hours time scale relevant for some learning and memory processes. In this abstract, studies of axonal function were continued by taking advantage of recent developments in micro-electrode array (MEA) technology, which has provided the ability to track propagating action potentials traveling across hundreds of sites by using stimulus-triggered averaging. Rat cortical neurons and glia were cultured over a novel MEA containing 11,011

densely-packed electrodes within 3.4 square mm (Frey et al. 2010). Live-cell images of single axons transfected with fluorescent protein were compared to the electrophysiological signals they produced. Many-fold velocity differences existed between neighboring segments (<10s of microns), and the velocity profile temporally varied across days. Future experiments will address what mechanisms could be regulating action potential conduction locally and whether or not this is important for neural information processing.

Title: Propagation of errors in metabolically constrained networks of excitatory and inhibitory neurons

Authors: *J. CHAPETON, R. GALA, A. STEPANYANTS;
Physics, Northeastern Univ., Boston, MA

Abstract: Long-term memories are stored in the strengths and patterns of synaptic connections. A memory of a sequence of events that plays out in time is recalled as the activity of neurons progresses from one network state to the next. In the absence of noise, such a memory sequence can be retrieved in its entirety. However, the stochastic nature of synaptic transmission can cause neurons to fire spontaneously or fail to generate action potentials. Clearly, memory retrieval has to be robust with respect to such errors; yet, it is not known how this robustness is achieved in cortical circuits of excitatory and inhibitory neurons. Thus, we examine the following questions. (1) Are the firing statistics of biological neural networks consistent with a regime in which errors are suppressed and do not disrupt memory retrieval? (2) How much noise can be tolerated by local cortical circuits during the memory retrieval process?
In order to quantitatively explore these questions we consider the model of steady-state learning. In this model a given cortical circuit in the adult functions in the state of maximal memory storage capacity, and learning of new memories is accompanied by forgetting of some of the old ones. Specifically, we analyze the retrieval of temporal sequences of associative memories stored in a network of robust McCulloch and Pitts neurons. During memory storage the neurons learn

by modifying the weights of their excitatory and inhibitory inputs in the presence of two biologically inspired constraints: (i) the firing thresholds of all neurons are kept constant, and (ii) the overall weight of connections received by each neuron (the L_1 norm) is fixed. As a result of the analysis we delineate the domain of excitatory and inhibitory firing frequencies in which memories can be recalled robustly.

Title: Two distinct origin of the active phases of the slow cortical rhythm in the somatosensory cortex of the ketamine-xylasine anesthetized rat

Authors: *R. FIÁTH[1], P. BEREGSZÁSZI[2], I. ULBERT[1,2];
[1]Res. Ctr. For Natural Sciences, Hungarian Acad. of Sci., Budapest, Hungary; [2]Fac. of Information Technol., Pázmány Péter Catholic Univ., Budapest, Hungary

Abstract: The slow cortical rhythm (SCR) emerges during slow-wave sleep or under anesthesia. The cellular counterpart of the SCR, the slow oscillation is characterized by rhythmic alternation of two phases: the active phase (up-state) with strong synaptic activity, massive cell firing and depolarized membrane potential, and the inactive phase (down-state) with hyperpolarized cells and neuronal silence. Current knowledge suggests that the SCR is mostly of cortical origin, spontaneous up-states may initiate at any point of the neocortex and the rhythm behaves as a traveling wave. Recent results obtained with optogenetic methods indicate a more prominent role

of the infragranular cortical layers in the generation of the SCR compared to supragranular layers: synchronous activity of a small cluster of mouse layer V pyramidal cells is able to start a new active phase, while layer III pyramidal cells do not have this ability. Based on the observations of other research groups, up-states can be evoked with brief sensory stimuli through the thalamorecipient layer IV as well. However, we assume that up-states initiate also spontaneously from layer IV, in the absence of stimulation. Our assumptions are supported by the fact that the cortex and thalamus form a complex, reciprocally connected network and by previous studies that state that the thalamus may have an important role in the generation of the SCR.

To test our hypothesis, we recorded the local field potential and the multiple-unit activity from the somatosensory cortex of ketamine-xylazine anesthetized rats with a laminar silicon multielectrode. Cortical layers were identified on the Nissl-staind coronal slices and assigned to the appropriate recording channels. For every up-state the layer with the earliest unit activity was computed.

Our preliminary results show that in a notable part of the experiments, beside up-states starting in layer V, are also a significant amount of active phases initiated in layer IV present. Furthermore, in some cases the number of spontaneously occuring up-states in layer IV exceeded the number of up-states with layer V onsets.

Based on these results we can conclude that in certain regions of the rat somatosensory cortex active phases of the SCR can originate spontaneously not only from layer V, but also from layer IV. These latter up-states are generated presumably in the thalamus and relayed to the cortex. However, it is possible that one part of these spontaneous, layer IV up-states are initiated by sensory stimuli coming from the outside world which are not registered during the experiments, e.g. the continuous mechanical stimulation of the skin on the trunk of the animal caused by breathing.

Title: The effects of propagation delays on spiking activity

Authors: *K. Y. TERRAZAS[1], W. TEKA[2], F. SANTAMARIA[3];
[1]Univ. of Texas At San Antonio, San Antonio, TX; [3]Biol., [2]Univ. of Texas at San Antonio, San Antonio, TX

Abstract: We are investigating the effects of axonal propagation velocities on coordinated transmission of synaptic information. For this purpose we have coded a computer program to simulate leaky integrate and fire neurons of different network sizes, connectivity, and distribution of axonal delays. Our modeling environment allows the implementation of arbitrary connectivity and propagation delays. The delay matrix is implemented as a three-dimensional buffer where instantaneous activity of the network is translated along the time axis. Such an environment allows us to investigate not only the traditional parameters of weight and network topology but also different distributions of delay times. The simulation environment is programmed in Matlab and has been compiled to run in parallel. We are particularly interested in studying how power-law axonal delays affect propagation of information in neural networks. First we have connected a neuron to an increasing number of cells that feedback to the main neuron with different types of delay distributions. We have calculated the firing rate properties and the cross and auto-correlations. Our results show the cumulative effects of long range correlations imposed by the network connectivity.

Title: Ultra-fast neuronal ensemble reaction times in cortical neurons under recreated synaptic background activity

Authors: *I. BIRO[1], D. LINARO[1], M. GIUGLIANO[1,2,3];
[1]Biomed. Sci., Univ. of Antwerp, Wilrijk, Belgium; [2]Brain Mind Inst., Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland; [3]Dept. of Computer Sci., Univ. of Sheffield, Sheffield, United Kingdom

Abstract: It has been shown that cortical ensembles, comprised of few thousand cells, can unexpectedly track fast varying input signals up to around 200 cycles/sec. They do so by relaying fast inputs downstream, in their spike trains. Such an input-output transfer bandwidth is in fact much wider than the limiting cutoff frequency imposed by the passive properties of individual neurons membrane (50 cycles/sec). This was first experimentally demonstrated by our group in 2008, performing in vitro a "linear system analysis" of output firing rates in response to current injection of sinusoidally modulated waveforms. These rapidly changing inputs were superimposed to randomly fluctuating signals, mimicking spontaneous synaptic activity observed in vivo.
However, the physiological activation of synaptic inputs to a neuron is mediated by ionotropic synaptic receptors (e.g., AMPAr, NMDAr, GABAa). This results not only in excitatory and inhibitory net currents, but also in a stimulus-dependent change of the overall effective membrane conductance of the postsynaptic cell. In order to include and study these effects in our experiments, we employed a real-time computer-controlled protocol (i.e., dynamic-clamp) to study input-output response properties of rat somatosensory cortical neurons from the layer 5 in acute brain slices. We asked whether neurons are able to track current- or conductance-based signals on a noisy conductance background. Our results clearly indicate that neurons receiving a barrage of emulated synaptic inputs, closely resembling the in vivo high-conductance state, have ultra-fast reaction times and track fast changing inputs. The input-output transfer bandwidth shows a similar upper limit of 200 cycles/sec, in both cases of current- and conductance-based signals. However, the effect of the background synaptic activation becomes prominent for slow varying input components, while it only marginally affects the firing rate modulation by fast varying components. Beyond the upper limit of the transfer bandwidth, background synaptic activity has no significant effect, as opposed to what reported in previous theoretical studies. The analysis of the input-output response phase-shift is also similar, comparing current- or conductance-based signals. In conclusion, we confirmed the validity of previous studies and extend them to more realistic physiological conditions.

Title: Optogenetic investigation of local inhibitory circuitries in the nucleus of the solitary tract

Authors: *J. A. CORSON[1], R. M. BRADLEY[2];
[2]Biologic and Materials Sci., [1]Univ. of Michigan, Ann Arbor, MI

Abstract: The rostral nucleus of the solitary tract (rNTS) is the first central target of primary orosensory nerve fibers. As such, it plays an essential role in the processing and coding of taste, tactile, and temperature sensory information from the oral cavity. The intrinsic circuitry within rNTS is likely integral in shaping the incoming information into both ascending (pontine-thalamo-cortical) and descending (intramedullary) efferent signals. Substantial subpopulations of interneurons in the rNTS are GABAergic and thus contribute to the transformation of incoming sensory afferent barrages into temporally modified spike trains. Despite this importance in shaping rNTS orosensory-evoked signaling, the organization of rNTS GABAergic circuits is unknown. To investigate the spatial patterning of GABAergic neurons presynaptic to identified subpopulations of neurons, we used a mouse model in which channelrhodopsin was expressed under the control of vesicular GABA transporter. Animals received small pressure injections of fluorescent microspheres into either the parabrachial nucleus or subjacent reticular formation to label either ascending or descending neurons respectively. Acute slices were prepared from these animals for in vitro patch clamp recording. GABAergic interneurons were activated with 473 nm laser illumination merged into the optical axis of the microscope. Focused laser illumination produced consistent saturated photocurrents in GABAergic neurons with high temporal and spatial resolution. While recording inhibitory postsynaptic currents in different rNTS neuron populations, the laser spot was systematically scanned over discrete portions of the rNTS to map out the GABAergic innervation onto the recorded neuron. Inhibitory maps will be compared for ascending and descending projection neurons as well as GABAergic interneurons. Neurons received inhibitory innervation from wide expanses of rNTS, often with focal spots of strong inhibition located in areas not immediately adjacent to the recorded neuron. This suggests that in addition to a low level of global inhibition, there are also specific subregions of rNTS that are able to strongly hyperpolarize individual neurons. This strong inhibition will likely induce alterations in repetitive discharge patterns through the numerous hyperpolarization-activated currents expressed in many rNTS projection neurons. The results of this study will provide valuable information into the mechanisms by which the rNTS is able to transform incoming sensory information into discrete efferent signals.

Title: Fast voltage sensitive dye imaging of functional connectivity in the rat retrosplenial cortex

Authors: *K. NIXIMA[1,2,3], T. KUROTANI[2,3], K. OKANOYA[1,2,3];
[1]Grad. Sch. of Arts and Sci., The Univ. of Tokyo, Tokyo, Japan; [2]ERATO Okanoya Emotional Information Project, Japan Sci. and Technol. Agency, Saitama, Japan; [3]Emotional Information Joint Res. Laboratory, Riken Brain Sci. Inst., Saitama, Japan

Abstract: The rodent granular retrosplenial cortex (GRS) has dense reciprocal connections with the anterior thalamic nuclei (ATN) and the hippocampal formation, hence playing a crucial role in some forms of learning and memory. In superficial layers of the GRS, distinctive pyramidal neurons, showing a late-spiking (LS) firing property, form prominent dendritic bundles in layer 1a co-localizing with the ATN termination patches. However, most previous interests were addressed to the anatomical aspects, and the detailed information about the functional connectivity within the GRS remains to be elucidated.
In this study, we conducted fast voltage sensitive dye (Di-4-ANEPPPS) imaging from slice preparations of the rat GRS, in order to clarify the detailed intracortical signal transmissions. In the coronal plane, layer 1a stimulation evoked excitatory synaptic transmission in layers 2-4 and subsequent excitation in layers 5-6. Each excitation in those layers was followed by transverse signal propagation within the layers, and spread to the dysgranular retrosplenial cortex (DRS). Interestingly, either superficial or deep layer stimulation induced monosynaptic inhibitory responses mainly in layers 2-4, which was confirmed by perfusing glutamate antagonists, DNQX and DL-APV. In the horizontal plane, layer 1a stimulation evoked similar spatio-temporal patterns. Compared with the coronal slices, layer 1a stimulation induced broader transverse signal propagation in deep layers. This propagation was not disrupted by a perpendicular cut in the deeper layers, indicating that the excitation was transferred by way of the superficial layers. The direction of the excitation propagation was predominantly from posterior to anterior, usually with less inhibitory responses compared with those observed in the coronal slices. In contrast to the layer 1a stimulation, the subiculum or corpus callosum stimulation mainly activated deep layer neurons of the GRS rather than superficial neurons.
In conclusion, signal inputs from the ATN can be conveyed to layers 5-6 neurons (and then to the neocortex or frontal robes), by LS-neuron network in superficial layers. Since the LS-neuron network is suggested to have a filtering role for the ATN signals, layers 5-6 neurons are likely to integrate filtered signals from the ATN with non-filtered (direct input) signals from the hippocampal formation. The spatio-temporal dynamics of neural activities in the GRS microcircuitry may thus be important for learning and memory.

Title: Layer V photo-stimulation efficiently recruits infragranular and supragranular cortical neurons

Authors: R. BELTRAMO, P. FARISELLO, *T. FELLIN;
Inst. Italiano di Tecnologia, Genova, Italy

Abstract: Recent *in vivo* reports demonstrate that layer V pyramidal neurons are fundamental in the regulation of the spontaneous network activity and that they efficiently propagate prolonged depolarizations within and across cortical layers. Since layer V pyramidal cells represent a major output of the cortical column and project to both cortical and extra-cortical areas, the spread of depolarization that follows the activation of layer V pyramids might be mediated by intra- or extra-cortical fibers. To discriminate between these two possibilities, we performed patch-clamp recordings in acute cortical slices in which the cortical circuitry was isolated from the rest of the brain. Using the transgenic mouse line *Rbp4-Cre,* which expresses the enzyme Cre in a subset of layer V neurons, we conditionally expressed the light-gated cation channel channelrhodopsin-2 (ChR2) through adeno-associated viral injections. We recorded in current-clamp configuration the responses of ChR2-negative neurons located in infragranular and supragranular layers, while stimulating the subpopulation of ChR2-positive cells in layer V. At their resting membrane potential, all recorded neurons responded to light stimulation with complex membrane depolarizations which were characterized by supra-millisecond latencies. These preliminary experiments suggest that intra-cortical projections are sufficient to propagate within and across cortical layers the depolarizing events that follow layer V photo-activation.

Title: Entorhinal cortical theta-frequency input to the dentate gyrus trisynaptically evokes hippocampal CA1 LTP *In vitro*

Authors: *J. STEPAN[1], J. DINE[1], T. FENZL[6], S. A. POLTA[2], A. URIBE[3], G. VON WOLFF[4], F. HOLSBOER[5], M. V. SCHMIDT[3], C. T. WOTJAK[2], M. EDER[1];
[1]Neuronal Network Dynamics, [2]Neuronal Plasticity, [3]Neurobio. of Stress, [4]Neuroimaging, [5]Max Planck Inst. of Psychiatry, Munich, Germany; [6]Dept. of Pharmacol. and Toxicology, Leopold-Franzens-University, Innsbruck, Austria

Abstract: There is substantial evidence that some forms of explicit learning in mammals require long-term potentiation (LTP) at hippocampal CA3-CA1 synapses. While CA1 LTP has been well characterized at the monosynaptic level, it still remains unclear how the afferent systems to the hippocampus can initiate formation of this neuroplastic phenomenon. Using a combination of fast voltage-sensitive dye imaging (VSDI) and field potential recording in an elaborate mouse brain slice preparation, we show that stimulus-evoked entorhinal cortical (EC) theta-frequency (5 Hz) input to the dentate gyrus highly effectively generates waves of neuronal activity which propagate through the entire trisynaptic circuit of the hippocampus ("HTC-Waves"). This flow of activity is markedly less pronounced during 1 and 20 Hz EC input and not inducible using a stimulation frequency of 0.2 Hz. HTC-Waves, which we also demonstrate in vivo, critically depend on frequency facilitation of mossy fiber to CA3 synaptic transmission. They precisely follow the rhythm of the EC input, involve high-frequency firing (>100 Hz) of CA3 pyramidal neurons, and induce NMDA receptor-dependent CA1 LTP within a few seconds. We additionally show that HTC-Waves are rapidly boosted by the cognitive enhancer caffeine (5 µM), the stress hormone corticosterone (100 nM), the endogenous cannabinoid reuptake inhibitor AM404 (10 µM), the antidepressants amitriptyline, clomipramine, fluoxetine, citalopram, fluvoxamine, venlafaxine, tianeptine and tranylcypromine (all of them in the low micromolar range), and the mood stabilizer lithium (0.5 and 1 mM). In contrast, chronic stress, the antipsychotic haloperidol (10 µM), and the anxiolytic agent diazepam (0.1 and 1 µM) considerably weaken HTC-Waves. Taken together, our study provides the first experimental evidence that synchronous theta-rhythmical spiking of EC stellate cells, as occurring during EC theta oscillations, has the capacity to drive induction of CA1 LTP via the hippocampal trisynaptic pathway. Moreover, we present data pointing to a basic filter mechanism of the hippocampus regarding EC inputs and describe an in vitro real-time imaging assay to reveal

pharmacologically and environmentally induced alterations in the “input-output relationship” of the hippocampal trisynaptic circuit.

Title: Finite-size effects identify feed-forward dynamics of neuronal avalanches

Authors: *S. YU, A. KLAUS, H. YANG, D. PLENZ;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Considerable effort is currently dedicated to identify mesoscopic brain dynamics by recording simultaneously from as many neurons as possible. For the mammalian cortex, high-density microelectrodes provide a restricted view into cortical dynamics that manifest at scales potentially much larger than the observation window. The finite-size effects of such ‘windowed’ recordings on characterizing the true neuronal dynamics of the much larger network are poorly understood. Here we study this problem by analyzing neuronal avalanches in ongoing local field potentials (LFPs) from awake macaque monkeys and neuronal modeling. We show that finite-size effects imposed by the recording window can be clearly identified and provide crucial insights into the feed-forward activity cascades that underlie scale-invariant neuronal avalanche dynamics. Spontaneous LFP activity (1 – 100 Hz) was recorded in superficial layers of pre-motor and prefrontal cortex in two awake macaque monkeys with chronically implanted, high-density 96-microelectrode arrays. Spatiotemporal LFP clusters were identified on the array and on compact sub-regions of the array corresponding to window size, N, ranging from $N = 10 – 95$. Clusters in each region organized as neuronal avalanches, i.e., the cluster size, s, followed a power law with exponent -1.5 up to N, beyond which the probability of cluster size declined steeply, referred to as the ‘finite-size effect’. Several additional observations were made. First, clusters with $s < N$ consisted mainly of non-repeating electrode activations. Thus, avalanches represent non-recurrent, feed-forward cascades. Second, clusters with $s > N$ reflect avalanches that activated all electrodes at least once in addition to electrode repeats. Thus, for $s > N$, the

avalanche size distribution captures the relatively small subset of avalanches that incorporate numerous repeats. Third, with increasing *N*, repeats increased for all cluster sizes $s < N$ and $s > N$. This reflects increasing dynamical re-activation of sites during avalanches with longer lifetimes and reduces the finite-size effect. These findings were confirmed in a model for N up to 625 that realized critical branching dynamics at the neuron level and provided a window of locally summed neuronal activity in a layer of LFP electrodes. In summary, the finite-size effect observed for neuronal avalanches reflects their nature of feed-forward cascades. We conclude that careful identification of finite-size effects allows for proper identification of the underlying dynamics despite windowing constraints when measuring from a subset of a neuronal population.

Title: Dorsal and ventral hippocampal CA1 pyramidal neurons activate distinct brain area: Optogenetic investigation using mouse fMRI

Authors: *N. TAKATA[1], Y. KOMAKI[2], Y. SAKAI[4], K. YOSHIDA[3], M. XU[3], K. HIKISHIMA[2], H. OKANO[2], M. MIMURA[3], K. F. TANAKA[3];

Abstract: Functional segmentation of the hippocampus along its dorsoventral axis has been proposed; dorsal hippocampus (DH) is involved in memory function while ventral hippocampus (VH) modulates emotional processes. Indeed, anatomical studies have revealed that extrinsic axonal projections from the field CA1 reaches over 50 areas and areal subdivisions and that these afferent fibers show distinct pattern depending on its origin (DH or VH). Gene expression research also demonstrated heterogenic spatial distribution patterns of some marker genes in the CA1 along the axis. Although these studies are suggestive of distinct function of DH and VH, physiological impact of DH- or VH-activity on other brain region would further deepen our understanding of functional differences of them. To this end, we combined functional MRI (fMRI) and a transgenic (Tg) mouse expressing a highly light-sensitive channelrhodopsin-2

mutant [ChR2(C128S)] in CA1 pyramidal neurons. Preliminary results show that illumination of DH or VH of an anesthetized Tg-mouse induced BOLD response in distinct area of the brain.

Title: Neuronal encoding and the site of action potential initiation

Authors: *M. A. VOLGUSHEV[1], V. ILIN[2], E. NIKITIN[3];
[1]Dept Psychol, Univ. Connecticut, STORRS MANFLD, CT; [2]Dept Psychol, Univ. Connecticut, Storrs, CT; [3]Inst. of Higher Nervous Activity and Neurophysiology, Russian Acad. of Sci., Moscow, Russian Federation

Abstract: Populations of neocortical neurons can encode rapidly changing signals and respond to subtle inputs fast, within few ms. Theoretical analysis of single-compartment models attributed such coding properties to action potential (AP) generators with fast onset dynamics. These models, however, do not take into account electrical compartmentalization of neurons. In neocortical neurons, membrane potential produced fluctuations produced by incoming inputs and the APs are usually recorded in the soma, while initiation of the APs takes place in the axon initial segment (AIS), at some distance from the soma and recording site.
Here we ask whether encoding properties of neurons depend on the site of AP initiation. Using whole-cell recordings in slices from rat neocortex we show that populations of layer 5 pyramidal neurons can encode fast input changes by phase-locking their firing to frequencies up to ~500-600 Hz. Using fast optical imaging with voltage-sensitive dyes we show, in accordance with prior reports, that APs in these neurons are initiated in the AIS, 50-55 μm from the soma. For

computer simulations, we constructed families of multicompartmental neuron models with systematically shifted site of AP initiation along the axon: in the axon hillock, proximal or distal axon initial segment and 1st to 4th node of Ranvier. In the models with Hodgkin-Huxley type sodium channels the encoding of high frequencies was improved when AP initiation site was shifted from the soma to the distal AIS or the first node of Ranvier, but deteriorated with further shift to the 2nd - 4th nodes. However, even with the optimal location of AP initiation site at 50-120 μm from the soma, the encoding of high frequencies in HH type models was significantly inferior to that in neurons. In the second and third families of models a small fraction (10%) of sodium channels with threshold-like activation or cooperative activation was added at the site of AP initiation. All other sodium channels in these models had HH type kinetics. Models with a fraction of threshold channels at the initiation site encoded high frequencies better than the neurons. Encoding in the models with a fraction of cooperative channels at the initiation site was better than in HH type models, but less robust than in models with a fraction of threshold channels. In contrast to HH type models, encoding of high frequencies in the models with a fraction of threshold or cooperative channels was optimal when spikes were initiated in the soma or axon hillock, but was slightly attenuated with the shift of AP initiation site away from the soma, most probably due to passive filtering of membrane potential fluctuations on their way to the AP initiation site.

Title: Effects of isoflurane on cortical UP state activity in brain slices

Authors: *H. HENTSCHKE[1], A. RAZ[2], B. M. KRAUSE[3], S. M. GRADY[2], M. I. BANKS[2]; [1]Anaesthesiol., Univ. Tuebingen, Tuebingen, Germany; [2]Dept. of Anesthesiol., [3]Neurosci. Training Program, Univ. of Wisconsin, Madison, WI

Abstract: Introduction: Loss of consciousness under volatile anesthetics is likely mediated via direct actions on the cortico-thalamic network. We have detailed knowledge of the molecular targets of these agents, and end effects on cortically mediated behaviors are similarly well described, but how these agents alter activity at the network level is unclear. Cortical UP states

represent all-or-none, synchronous, propagating bouts of network activity. UP states and the aroused cortical state share key characteristics, and evidence suggests parallel continua from bistable UP/DOWN to desynchronized network activity and from the unconscious to the aroused behavioral state. Thus, modulation of UP states by anesthetics may shed light on the mechanisms of these agents' hypnotic effects.
Methods: Acute auditory thalamocortical (TC) brain slices were prepared from 4-13 wk mice. Local field potentials (LFPs) and multiunit activity (MUA) were recorded using silicon multielectrodes (16 shanks, 100μm spacing, 1 site/shank) oriented either perpendicular to the pial surface or rostro-caudally in layer 5 of auditory cortex. TC and corticocortical (CC) afferents were stimulated using bipolar tungsten electrodes. Cocultures of two cortical slices were prepared from P3 mice and used after 2 wk in vitro, at which time the pair of slices had established mutual synaptic connections. LFPs and MUA were recorded with glass electrodes (one in each slice).
Results: Both acute and cultured slices dwelled primarily in DOWN states, with occasional (acute) or frequent (cultured) spontaneous UP state transitions. Afferent stimulation reliably evoked UP states in all slices. In acute slices, thresholds were lower for TC versus CC stimulation, but for both stimuli UP states originated in layer 5 and spread to supragranular layers. UP state activity propagated several millimeters along the layers at a rate dependent on stimulus efficacy (range 8 - 42 μm/ms). In cultures, spontaneous or stimulated UP states originating in one slice triggered UP states in the other with lags of 10 - 300 ms. Isoflurane (0.5 - 1%) increased thresholds for evoking UP states and decreased their propagation velocity (acute), shortened stimulated and spontaneous UP states and depressed the frequency of occurrence of spontaneous UP states (cultured) and decreased trial-by-trial variability of LFP and MUA activity (both).
Conclusions: Isoflurane suppresses UP state activity in cortical networks, and may increase reproducibility of stimulated activity by suppressing background activity outside UP states.

Title: Reliability of network behaviour depends on excitation/inhibition balance and distribution of synaptic weight

Authors: *S. RAY, U. S. BHALLA;
NCBS, Bangalore, India

Abstract: We investigated the behaviour of a neuronal network model of thalamus to cortical layer 4 circuit with varying number of inhibitory neurons. In addition, we also studied how the distribution of synaptic weights affects the network behaviour.
We ported components from a published model (Traub et al 2005) to the Multiscale Object-Oriented Simulation Environment (MOOSE) to construct a network of excitatory spiny stellate (SS) cells of cortical layer 4, inhibitory deep basket (DB) and deep LTS (DLTS) cells. This network received inputs from a set of thalamocortical relay (TCR) cells stimulated electrically. The cell populations were connected via GABAA or AMPA and NMDA synapses. We simulated multiple instances of this network with varying number of deep basket cells while keeping the total synaptic conductance on each postsynaptic cell constant. The synaptic strengths were either constant between a pair of cell types or was normally distributed. Later we simulated the network with lognormal distribution of the AMPA conductance.
The SS population in the network displayed spontaneous synchronized spiking. As the number of inhibitory cells increased, the period of this synchronized spiking became more variable and smaller fractions of SS cells participated in the synchronized events. In these simulations the stimulus via TCR cells had little effect on the SS population. On the other hand, when the AMPA conductances between each pair of cell types were lognormally distributed, such that there were only a few strong synapses with many weak synapses, the spontaneous population spiking was eliminated and there was synchronized population spiking in response to the stimulus.
Inhibitory interneurons, though few in number, have strong effect on network behaviour. We find that the balance of excitation and inhibition is crucial but so is the synchrony of inhibition as tested by scaling the number of basket cells while keeping the total synaptic input constant. Moreover the distribution of synaptic weights is important in eliciting response to stimulus. A lognormal distribution is most effective for this. Our work shows that detailed experimental investigation of these aspects will be vital in understanding cortical processing.

Title: Exploration of the input-output relation of granule cells in the dentate gyrus

Authors: A. D. MADAR[1], L. A. EWELL[2], *M. V. JONES[1];
[1]Dept Neurosci., Univ. Wisconsin Madison, MADISON, WI; [2]Neurobio. Section, Univ. of California,, San Diego, CA

Abstract: Although extensive work has been done to understand hippocampal processing, a clear mechanistic view of how information is processed at the very first stage, inside the Dentate Gyrus (DG), is still elusive. To rigorously explore the computational role of the DG requires knowledge of both the input and output patterns. It is difficult to obtain this information in vivo, whereas the accessibility of the in vitro brain slice provides an ideal, yet largely unexploited, platform. Input to the DG arrives via the perforant path from entorhinal cortex (EC), whereas Granule Cells (GCs) constitute the output to the CA3 region. To explore the input-output relation of the DG, we performed whole-cell recordings of GCs in acute slices of mouse brain, while stimulating the lateral perforant path (LPP) or the medial perforant path (MPP) arising from the lateral or medial entorhinal cortex (LEC or MEC) respectively. Poisson stimulus trains (100 µs pulses, 0.1-10 mA) were delivered through a <5 µm theta pipette with a mean rate of 10 Hz, a frequency shown to preferentially drive spike and burst generation in GCs (Ewell & Jones, 2010). Alternating between voltage- and current-clamp, we recorded postsynaptic currents (i.e., synaptic input) and membrane potential fluctuations (i.e., spiking output) during the presentation of 10 different stimuli trains. This way, it was possible to measure how incoming signals are integrated by GCs.
First we characterized what kind of inputs make GCs fire by averaging the LPP or MPP stimulus trains that immediately preceded each spike. These Spike-Triggered Averages (STA) showed that different GCs were responsive to different spatial and temporal patterns, some being more sensitive to LPP inputs, others to MPP or equally responsive to both. To further understand how input patterns are transformed into spikes, we asked what patterns of postsynaptic currents lead to action potentials. To do this we performed STA on the current traces assumed to be good estimates of the current fluctuations when the membrane potential was recorded. Surprisingly, 5/7 GCs showed that the EPSC preceding a spike was on average closely followed by a large secondary EPSC. Indeed, looking at individual spike-triggered current waveforms, a large post-

spike EPSC was often present. In all GCs, Principal Component Analysis on the spike-triggered ensemble of current waveforms detected multiple clusters, suggesting that GCs spike in response to a variety of current waveform shapes, some of which have a late EPSC. The source of the late EPSC is not clear but could be explained by feedback excitation via mossy cells or by back-propagating action potentials unmasking NMDA currents.

Title: The GABAB modulation affects recurrent horizontal flow of activity & local synchrony in an 'Up-State' model of cortical functioning

Authors: *R. G. PORT[1], M. F. MCMULLEN[2], G. C. CARLSON[2];
[1]Neurosci. Grad. Group, Univ. Of Pennsylvania, Philadelphia, PA; [2]Psychiatry, Univ. of Pennsylvania, Philadelphia, PA

Abstract: GABAergic compounds have recently been shown efficacious in the partial treatment of Autism Spectrum Disorders and related neurodevelopmental diseases. A possible substrate for these treatments could be the reduction of local circuit hyperconnectivity, and recovery of network synchrony. As the first step in a series of experiments, we have modeled cortical functioning to thalamic input using a media that promotes the creation of both spontaneous, and thalamic stimulation evoked recurrent cortical network activity. Recordings of network activity were acquired using both voltage sensitive dye imaging of auditory cortex and electrodes placed in supragranular/granular lamina of auditory cortex for local field potentials. Data was then analyzed using Igor and the Matlab toolbox Fieldtrip to examine spread and frequency coherence profiles of circuit activity. After 30 minutes of baclofen exposure, both the propagation of recurrent network activity, and measures of local synchrony (gamma-band activity) are reduced. This work is part of an ongoing project studying neural activity abnormalities in early auditory processing for Autism Spectrum Disorders. This work was supported by NIH/NICHD 1R01HD062577-01.

Title: Regulation of dynamic range in CA1 pyramidal neurons by feedforward inhibition and background noise

Authors: *A. KHUBIEH[1,2], S. RATTE[1], S. A. PRESCOTT[1,3];
[1]Neurosciences and Mental Hlth., Hosp. For Sick Children, Toronto, ON, Canada; [2]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland; [3]Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Regulating the gain of a neuron's input-output curve is crucial for insuring that this neuron can encode over an appropriate range of stimulus intensities. It has been argued that pyramidal neurons in the CA1 region of hippocampus have very steep input-output curves in response to Schaffer collateral stimulation, and that it is by activating more neurons that the network as a whole (rather than any single neuron) can encode the stimulus intensity. The balance of signal-dependent excitation and feedforward inhibition (FFI) plays an important role in that process. However, other studies have shown that background synaptic activity is also important for gain control. We hypothesized that background activity would reduce input-output gain, broadening the encoding range.
To test our hypothesis, we recorded CA1 pyramidal neurons from a rat hippocampal slice preparation. We applied stimuli in one of two ways: by stimulating the Schaffer collaterals or by injecting virtual synaptic waveforms directly into the recorded neuron using dynamic clamp. In both experiments, neurons were subjected to background activity simulated using two Ornstein-Uhlenbeck processes, each for excitatory and inhibitory conductance, and applied through dynamic clamp. We then used computer simulations and mathematical analysis to test different values of input synchrony and latency to inhibition to explore how these parameters impact the input range in this modified context. In each experiment, we measured the probability of spiking induced by the stimulation for different input strengths.
Comparing conditions with and without background activity, we found that neurons displayed a broader dynamic range under the realistic conditions (i.e. with background activity). By testing different background activity parameters, we found that shunting is responsible for a depolarized spiking threshold whereas increasing noise is responsible for decreasing the input-output gain.

Finally, simulations showed that diverse combinations of parameters of FFI adjust the input range in different ways.
Our results suggest individual CA1 pyramidal neurons can encode a broad range of stimulus intensities when they operate under noisy conditions. But because the response of any one neuron is noisy, the output from a set of neurons must be considered in order to decode the intensity of any one stimulus. FFI still contributes to regulating the dynamic range.

Title: Traveling alpha waves in the human electrocorticogram

Authors: *H. ZHANG[1], A. D. SHARAN[3], M. R. SPERLING[3], J. JACOBS[2];
[2]Biomed. Engin., [1]Drexel Univ., Philadelphia, PA; [3]Thomas Jefferson Univ., Philadelphia, PA

Abstract: Over decades of research, brain oscillations have been shown to play a critical role in various aspects of human brain function. In particular, oscillations in the theta and alpha bands (4-16 Hz) have been shown to vary in amplitude in relation to neural processes related to memory and cognition. In addition to these amplitude changes, research in animals has shown that brain oscillations exhibit complex patterns of phase changes across space, including traveling and spiral waves across the cortex and hippocampus. However, little evidence for similar patterns in humans has been found. We developed a new method to detect spatial patterns of brain oscillations and used this approach to probe human brain oscillations in electrocorticographic recordings from epilepsy patients performing a memory task. We found spatial patterns of synchronized oscillations in a range of frequencies, including the theta, alpha and beta bands. These patterns included both traveling and standing waves, as well as complex hybrid patterns. We analyzed the direction of these traveling waves and found that alpha waves during the task emanate outward from the temporal lobe and travel to the frontal and occipital lobes. Our results support the hypothesis that traveling waves aid in information flow and help to coordinate large-scale brain networks. We discuss the possible role of alpha oscillations in gating top-down and bottom-up information flow during human memory processing.

Title: Repeated nerve block using charge balanced direct current through high surface area electrodes

Authors: *T. L. VRABEC[1], M. FRANKE[1], J. S. WAINRIGHT[2], N. BHADRA[1], N. BHADRA[1], K. L. KILGORE[3,1,4];
[1]Biomed. Engin., [2]Chem. Engin., Case Western Reserve Univ., Cleveland, OH; [3]Orthopedics, MetroHealth Med. Ctr., Cleveland, OH; [4]Stokes Cleveland Dept. Veterans Affairs Med. Ctr., Cleveland, OH

Abstract: There are many neurological diseases that result in undesirable neural activity such as spasticity, movement disorders, and chronic pain of peripheral origin. Existing treatment options such as pharmaceuticals are insufficiently effective, and can result in significant side effects. A fast acting, reversible electrical conduction block is an advantageous option for meeting these needs. KiloHertz Frequency Alternating Current (KHFAC) has been shown to provide a fast acting nerve block that is quickly reversed when the KHFAC is halted. One drawback of KHFAC is that when it is first initiated, a brief burst of action potentials occurs which can cause undesirable effects. This "onset response" can be eliminated by briefly applying direct current (DC) block to electrodes flanking the KHFAC electrode. One obstacle to this method is the occurrence of neural damage from the DC due to electrochemical reactions at the electrode-tissue interface. An electrode design that can deliver DC block while not producing the electrochemical products might prevent nerve damage. The production of electrochemical products can be measured by cyclic voltammetry to determine the water window, which is the region where neither oxidation nor reductions occurs. There are several types of electrode coatings (e.g. platinum black, iridium oxide) that can increase the capacitance of the electrode, allowing more charge to be delivered while remaining within the water window. Monopolar nerve cuff electrodes were fabricated using platinum foil and then platinized in chloroplatinic acid solution to create platinum black coatings with different charge capacities. Typical values are in the range of 18mC to 21 mC. These electrodes were tested in acute experiments on the rat sciatic nerve using current-controlled, charge-balanced DC (CBDC) waveforms. The DC waveforms were repeatedly applied for 200 cycles of DC delivery or until nerve conduction was

compromised. Each cycle consisted of a 4 second ramp down, a 7 second plateau, and a 2 second ramp up for a total of 2600 sec of DC delivery over 200 cycles. The reduction of nerve conduction was measured by stimulating the nerve proximal and distal to the blocking site and comparing the force output of the muscle. The platinum black electrodes were capable of delivering the full 200 cycles (3200 mC) without any reduction in nerve conduction.

Title: Combined no-onset KHFAC+DC nerve block without nerve damage

Authors: *M. FRANKE[1], T. L. VRABEC[1], J. L. WAINRIGHT[1], N. BHADRA[1], N. BHADRA[1], K. L. KILGORE[2,3,1];
[1]Case Western Reserve Univ., Cleveland, OH; [2]Metro Hlth. Med. Ctr., Cleveland, OH; [3]Louis Stokes VA Med. Ctr., Cleveland, OH

Abstract: Kilo-Hertz frequency alternating current waveforms (KHFAC) have been shown to provide rapid, complete and fully reversible nerve block for durations up to 60 minutes. Chronic preclinical and pivotal clinical studies have shown efficacy and first safety data for an implementation of KHFAC block in applications for pain and obesity. However, one major side effect of this electric block has not been addressed so far: whenever KHFAC block is initiated, there is an intense transient activation of nerve fibers, termed the onset-response. The onset-response can last for seconds and has the potential to cause discomfort or pain to the patient, limiting potential clinical applications.
A ramped direct current (DC) waveform can produce nerve block without an onset-response. A brief (less than ten seconds) DC block through a separate electrode can prevent transmission of

the onset response produced by the KHFAC, while continued block is then maintained by KHFAC waveforms. A previous study showed that though this strategy worked, it resulted in rapid permanent nerve conduction failure if the injected DC charge was un-balanced. Change in nerve conduction occurred within 30 sec and complete permanent nerve conduction failure occurred within 60 sec of cumulative DC delivery. High surface area electrodes and the use of charge-balanced DC (CBDC) waveforms can solve this problem by ensuring that the electrode voltage during the CBDC remains within the water window (potential difference of -0.6 V to +0.9 V vs Ag/AgCl).
This study combined ramped CBDC and KHFAC waveforms to achieve an electric nerve block. Two separate block electrodes were acutely implanted on the rat sciatic nerve. The KHFAC electrode was located proximal to the high-surface area CBDC electrode. The block waveforms were initiated sequentially. After a full sciatic nerve (motor) block was achieved with the CBDC waveform, KHFAC block was initiated. While the sciatic nerve block was maintained by KHFAC, DC was charge balanced and then terminated. Nerve conduction integrity was monitored by comparing muscle forces produced by supra-threshold activation from an electrode proximal to both block electrodes with that from an electrode distal to both block electrodes. The results showed consistent “no-onset block” by using this combined nerve block method. Repeated CBDC block of durations up to 13 seconds each (plateau current range: -1.2 to -2.2 mA), followed by KHFAC block for up to 120 seconds (voltage range: 8 to 10 Vpp, 20 kHz) were applied for up to 30 cycles. We were able to show that CBDC block did not adversely affect nerve conduction with over 300 seconds of cumulative CBDC block time.

Title: Clustered thalamocortical input onto layer 5 pyramidal neurons detected using quantitative large-scale array tomography

Authors: *J.-C. RAH[1,2], E. BAS[1], J. COLONELL[1], Y. MISHCHENKO[3], B. KARSH[1], R. FETTER[1], E. MYERS[1], D. CHKLOVSKII[1], K. SVOBODA[1], T. HARRIS[1], J. ISAAC[2]; [1]Janelia Farm Res. Inst. of Hlth., Bethesda, MD; [3]Dept. of Engineering, Toros Univ., Yenisehir, Turkey

Abstract: The subcellular locations of synapses on pyramidal neurons strongly influences dendritic integration and synaptic plasticity. Despite this, there is little quantitative data on spatial distributions of specific types of synaptic input. Here we use array tomography (AT), a high-resolution optical microscopy method, to examine thalamocortical (TC) input onto layer 5 pyramidal neurons. We verify the ability of AT to identify synapses by means of parallel electron microscopic analysis. We then use large-scale AT to measure TC synapse distribution in a 1.00 x 0.83 x 0.21 mm^3 volume of mouse somatosensory cortex. We found that TC synapses primarily target basal dendrites in layer 5, but also make a considerable input to proximal apical dendrites in L4, consistent with previous work. However, we also found that TC inputs are biased towards certain branches and, within branches, synapses show significant clustering with an excess of TC synapse nearest neighbors within 5-15 um compared to a random distribution. Thus, we show that AT is a sensitive and quantitative method to map specific types of synaptic input on the dendrites of entire neurons. We anticipate that this technique will be of wide utility for mapping functionally-relevant anatomical connectivity in neural circuits.

Title: Neuronal antioxidant defense contribution of astrocytes-derived exosomes containing ascorbic acid

Authors: *P. TRONCOSO ESCUDERO[1], F. BELTRÁN[1], F. COURT[2], M. CASTRO GALLASTEGUI[1];
[1]Univ. Austral De Chile, Valdivia, Chile; [2]Pontificia Univ. Católica de Chile, Santiago, Chile

Abstract: Astrocytes have long been considered as just providing trophic support for neurons in the central nervous system. However, from few decades ago, several studies have demonstrated astrocytic importance in many functions such as neurotransmission, redox balance, metabolite and electrolyte homeostasis, among others. Ascorbic acid is a powerful antioxidant which is concentrated in brain. During synaptic activity ascorbic acid is released by astrocytes and taken up by neuronal cells. In neurons ascorbic acid is utilized to maintain redox balance and to modulate neuronal metabolism. Molecular and cellular basis of ascorbic release is not fully understood. In this work we studied ascorbic acid release from astrocytes through exosomes, extracellular microvesicles and hemichannels. Microvesicles and exosomes were purified from supernatant of primary cultures of cortical astroglial cells and human astrocytes cell line by centrifugation and ultracentrifugation, respectively. HPLC-detected ascorbic acid was released through exosomes and microvesicles in astrocytes. Also, the application of LaCl3, a hemichannel inhibitor, decreased ascorbic acid efflux suggesting an important role of connexins in ascorbic acid release from astrocytes. Finally, we demonstrated that ascorbic acid-containing exosomes derived from astrocytes is able to modulates the expression pattern of proteins related to ascorbic acid recycling and homeostasis in neuronal cells. Mechanisms of ascorbic acid exportation form glial to neuronal cells are indispensable to maintain the correct neuronal function. Impaired ascorbic acid release through these mechanisms could be related to redox and metabolic failures described in neurodegenerative diseases. FONDECYT1110571. DID-UACh.

Title: Noradrenaline attenuates hydrogen peroxide-induced cell death of astrocyte through the increase in the level of intracellular glutathione

Authors: *H. KADOI, Y. YOSHIOKA, A. YAMAMURO, Y. ISHIMARU, S. MAEDA; Setsunan Univ., Hirakata, Japan

Abstract: Noradrenaline (NA) has been known to modulate the functions of astrocytes. However, the effect of NA on the antioxidative capacity of astrocytes has been poorly investigated. In this study, we investigated the effect of NA on hydrogen peroxide (H_2O_2) toxicity in human astrocytoma U-251 MG cells. Cell viability was estimated by a colorimetric MTT assay, and intracellular glutathione (GSH) level was determined by DTNB recycling assay. Treatment of U-251 MG cells with H_2O_2 for 24 h induced cell death in a concentration-dependent manner. Pretreatment with NA (1-100 μM) for 24 h concentration dependently attenuated the H_2O_2-induced cell death. The cytoprotective effect of NA was inhibited by a β-adrenoreceptor antagonist propranolol, and pretreatment with a β-adrenoreceptor agonist isoproterenol (30-100 μM) attenuated the H_2O_2-induced cell death. Treatment with NA (1-100 μM) for 24 h concentration-dependently increased intracellular GSH level. In the presence of DL-buthionine-[S,R]-sulfoximine, a GSH synthesis inhibitor, the increase of intracellular GSH and the cytoprotection by NA were abolished. The NA-induced increase in intracellular GSH was inhibited by propranolol. Western blot analysis revealed that NA increased the level of glutamate-cysteine ligase (GCL), the rate-limiting enzyme in GSH synthesis. The induction of GCL protein by NA was inhibited by propranolol. The cytoprotective effect, the increase of intracellular GSH and the induction of GCL protein by NA were inhibited by a β_3-adrenoreceptor antagonist SR59230A, but not by a β_1-adrenoreceptor antagonist atenolol and a β_2-adrenoreceptor antagonist butoxamine. These results indicate that NA protects U-251 MG cells against H_2O_2-induced death through the increase in the level of intracellular GSH, and that NA increases the intracellular GSH level through the induction of GCL protein via β_3-adrenoreceptor stimulation.

Title: Noradrenaline protects neurons from hydrogen peroxide-induced death by increasing the supply of glutathione from astrocytes

Authors: S. MAEDA[1], A. YAMAMURO[1], Y. ISHIMARU[1], *Y. AGO[2], Y. YOSHIOKA[1]; [1]Setsunan Univ., Hirakata, Japan; [2]Osaka Univ., Suita/Osaka, Japan

Abstract: Hydrogen peroxide (H_2O_2) has been implicated in a variety of neurodegenerative disorders, such as Parkinson's disease. Astrocytes express many types of functional neurotransmitter receptors, and play a significant role for neuronal survival by supplying antioxidants such as glutathione (GSH) to neurons. Recently, we found that noradrenaline (NA) increased GSH in astrocytes. Thus, NA may protect neurons from oxidative stress-induced death by increasing the supply of GSH from astrocytes to neurons. In this study, we investigated the neuroprotective effect of NA by using the co-culture system of human neuroblastoma SH-SY5Y cells and human astrocytoma U-251 MG cells. We established SH-SY5Y cells overexpressed green fluorescence protein (GFP), and the cell viability was determined based on the morphology of GFP-positive cells under a fluorescence microscope. SH-SY5Y cells were co-cultured with U-251 MG cells as a mixture (mixed co-culture) or separately using culture insert (separated co-culture). To investigate the intracellular GSH level in SH-SY5Y cells in mixed co-culture, the cells were stained with reduced GSH-reactive probe monochlorobimane, and were analyzed by Cellomics ArrayScan. Pretreatment with NA (10-30 μM) for 24 h protected SH-SY5Y cells from H_2O_2-induced death in mixed co-culture, but not in single culture. NA increased the intracellular GSH levels of SH-SY5Y cells in mixed co-culture, but not in single culture. DL-buthionine-[S,R]-sulfoximine, a GSH synthesis inhibitor, negated the cytoprotective effect of NA in mixed co-culture. In separated co-culture with U-251 MG cells, NA failed to increase the intracellular GSH levels in SH-SY5Y cells and did not protect the cells from H_2O_2-induced cell death. These results indicate that NA protects SH-SY5Y cells from H_2O_2-induced death by increasing the supply of GSH from U-251 MG cells, and that the supply of GSH requires direct cell-cell contact between SH-SY5Y cells and U-251 MG cells.

Title: *In vitro* characterization of glial-derived neurotrophic factor upregulation, receptor internalization, and antioxidant adaptations to oxidative stress

Authors: *C. E. BOND, J. CRANMORE, S. FREGOSO, G. L. WRIGHT, D. B. HOOVER; Dept. of Biomed. Sci., Eastern Tennessee State Univ., Johnson City, TN

Abstract: Reactive astrogliosis, characterized by glial inflammation and proliferation, is the hallmark feature of both acute and chronic central nervous system damage in a majority of degenerative pathologies, including Alzheimer's disease, Parkinson's disease, and amyotrophic lateral sclerosis (ALS), the three most common degenerative brain disorders. Astroglia control the supply of metabolites through the blood-brain barrier, modulate signal transmission at the synapse, activate microglia in response to damage, and release trophic factors, such as glial-derived neurotrophic factor (GDNF) and neurturin (NTN), essential for neuronal proliferation and survival, during development and throughout adulthood. Although early experiments demonstrated that GDNF & NTN can rescue degenerating dopamine neurons in animal models of Parkinson's disease and enhance survival of cultured cholinergic motor neurons, results in human clinical trials have been disappointing.

Few studies have focused on the effects of these trophic factors on the cells that produce them, despite evidence that GDNF exerts its effect on neurons indirectly by stimulating growth factor release from intermediary glial cells, and confirmation that astroglia express cell surface receptors for both NTN & GDNF. In addition, despite the importance of stress-induced glial dysregulation in perpetuating degenerative processes, little is known about the cellular actions of these trophic factors under stress conditions. To clarify these mechanisms, this study examines oxidative stress-induced changes in GDNF-family gene expression, mitochondrial function and biochemical responses in primary cultures of astroglia from wild-type C57BL/6 and a NTN knockout mouse model for comparative studies. Main Findings: Quantitative real-time PCR revealed dose-dependent increases in GDNF and GFRα2 gene expression after H_2O_2 exposure, accompanied by changes in protein levels as determined by Western blotting and immunostaining. Glial cells treated with NTN also increased surface expression of GFRα2. We observed alterations in glial mitochondrial bioenergetic profiles, changes in intracellular antioxidant balance and altered mitochondrial inner membrane protein 8A (Timm8A) staining, in response to oxidative stress. Since GDNF & NTN are well-documented neuronal reparative factors, these studies hold potential for enhanced understanding and manipulation of glial-neuronal interactions in therapeutic strategies for neurodegenerative diseases.

Title: Age-dependent contribution of nitric oxide synthase to ischemic white matter injury

Authors: *S. BALTAN, J. ZALESKI, A. BACHLEDA, A. RUNKLE, S. BRUNET;
Dept. of Neurosciences, Cleveland Clin., Cleveland, OH

Abstract: Human brain comprises gray and white matter (WM) in equal volumes, which means that injury sustained after a stroke involves both. In addition, stroke risk increases considerably with age. Ischemic injury is a result of converging ionic, excitotoxic and oxidative stress pathways in young WM. In older WM the injury is mediated by enhanced excitotoxicity due to an earlier and more robust glutamate release. Recently we showed that even after maximal glutamate accumulation, preserving mitochondrial dynamics and ATP levels promote axon function recovery in young and old mouse optic nerves (MONs) suggesting that mitochondria related oxidative stress is a common component of ischemic injury in WM across irrespective of age. In this study we investigated whether blocking nitric oxide synthase (NOS) activity before or after a period of oxygen glucose deprivation (OGD) promoted functional recovery in an age-dependent manner.

Isolated MONs from young and old (1 and12 month) Swiss Webster (SW) or C57BL/6 (BL6) mice were used to ascertain quantitative measurements of WM function and structure. To support a biological basis for NOS inhibitor nitro-L-arginine methyl ester (LNAME) action on axon function, we evaluated the expression and localization of brain NOS (bNOS) using immunohistochemistry in combination with confocal microscopy. The expression of bNOS co-localized with GFAP (+) astrocyte nuclei, cytoplasm, end-feet as well as NF200 (+) axons. The pattern of bNOS expression paralleled astrocyte morphology with age and became more punctate in appearance. Evoked compound action potentials (CAPs) recovered to 21.8 ± 2.8% (n=18) after 60 min of oxygen glucose deprivation (OGD) in young BL6 MONs. Pretreatment of MONs with L-NAME (200 µM) promoted CAP recovery to 69.4 ± 11.3 % (n=8) compared to OGD while CAPs recovered to 39.9 ± 4.4% (n=11) when LNAME was applied after the end of OGD. Pretreatment of MONs from 1 or 12 month old SW with LNAME improved CAP recovery to 49.6 ± 3.7% (n=8, vs OGD 21.3 ± 3.7%, n=12) or to 51.1 ± 9.3% (n=7, vs OGD 5.7 ±1.7%, n=8) respectively. LNAME application after the end of OGD failed to promote aging axon function (8.8 ± 3.5%, n=6). Changes in NOS activity may help reveal age-dependent oxidative injury mechanisms involved in ischemic WM injury.

Title: Pathways for physiological accumulation of polyamines in astrocytes

Authors: *Y. RIVERA[1], M. INYUSHIN[1], Y. V. KUCHERYAVYKH[1], M. SALA-RABANAL[4], L. Y. KUCHERYAVYKH[2], J. BENEDIKT[1], A. ZAYAS-SANTIAGO[3], R. W. VEH[5], C. G. NICHOLS[4], M. J. EATON[2], S. N. SKATCHKOV[1];
[1]Physiol., [2]Biochem., [3]Pathology and Lab. Med., Univ. Central Caribe, Bayamon, Puerto Rico; [4]Cell Biol., Washington Univ. Sch. of Med., Saint Louis, MO; [5]Charite, Berlin, Germany

Abstract: The polyamines (PAs), spermine (SPM), spermidine (SPD) and putrescine (PUT) are small aliphatic amines that regulate multiple biological processes and are ubiquitous in all organisms and essential for life. The endogenous PAs, specifically SPD and SPM, strongly affect various ion channels and receptors in the brain and exert neuroprotective, antidepressant, antioxidant and further effects. PAs of the central nervous system are predominantly localized in glial cells, while neurons only contain low SPM concentrations (Laube and Veh, 1997; Skatchkov et al., 2000). However, glial cells lack the enzymes for SPD/SPM synthesis (Madai et al., 2012; Kraus et al., 2006; 2007; our preliminary data), and very little is known about the mechanisms of transport of SPD and SPM in these cells. The purpose of the present study is to investigate the possible pathways for PAs transport through the glial membrane. First, we showed that exogenously applied spermine can be taken up by and accumulated in astrocytes. We applied exogenous biotinylated-SPM (B-SPM) to astrocyte cultures in the presence of physiologically high concentrations of divalents (extracellular calcium and magnesium 2 mM). We visualized the SPM that was taken up into the cells using rhodamine conjugated with avidin and confocal microscopy. A dose dependent (20, 40, and 80 μM) uptake of B-SPM into astrocytes was observed. There are several potential pathways for SPM uptake by astrocytes. Our

results now point to two likely major pathways for SPM/SPD uptake into astrocytes. The first likely pathway for PA transport is through connexin hemichannels. We found that SPM may permeate the astrocytic membrane through Cx43 hemichannels because blockers of Cx43 hemichannels as well as siRNA against Cx43 abolished SPM, SPD and PUT currents. The second likely pathway for SPM/SPD uptake into astrocytes is through polyspecific organic cation transporters (OCTs). Using RT-PCR, we found that astrocytes express OCT1 and 3. Furthermore, we have recently shown that organic cation transporters (OCTs) heterologously expressed in Xenopus oocytes may take up a variety of PAs (Sala-Rabanal et al., 2013). Taken together, we suggest that in resting physiological conditions, when Cx-43 may be kept at low open probability by extracellular calcium and magnesium, the OCTs play a major role for PA uptake. Alternatively, when neuronal firing causes decreases in extracellular concentrations of Ca^{+2} and Na^{+}, the Cx43 pathway for release and uptake of PAs may become important.

Title: Sex differences in glia activity within the periaqueductal gray: Role in pain and analgesia

Authors: *L. N. EIDSON[1], L. M. BUTKOVICH[2], H. H. DOYLE[2], A. Z. MURPHY[2];
[2]Neurosci. Inst., [1]Georgia State Univ., ATLANTA, GA

Abstract: While morphine is one of the most effective analgesics available, females typically require 2-3 times more morphine than males to experience the same level of analgesia. The midbrain periaqueductal gray (PAG) is a central locus in pain signaling and opioid action. Recent studies suggest that morphine binds to the innate immune receptor toll-like receptor 4 (TLR4) on glia, resulting in increased activation of microglia and astrocytes and opposition of morphine analgesia. Here we test the hypothesis that the sexually dimorphic effects of morphine are due to sex differences in morphine-induced glial activity in the PAG. Specifically, we hypothesize that morphine increases PAG glial cell activity to a greater extent in females as compared with males, resulting in greater opposition of morphine analgesia.
Male and female rats were sacrificed 15, 30, and 60 minutes following subcutaneous morphine

(or equivolume saline), and tissue from the PAG was stained immunohistochemically to visualize microglial and astrocytic cell activity. Our results support our hypothesis of sex differences in glia expression within the PAG. Specifically, while baseline glia activity in the PAG of male brains exceeded that of females, morphine administration resulted in a significantly greater activation of glia in females in comparison to males at all time points.
To test the hypothesis that sex differences in morphine activation of glia contributed to sex differences in morphine analgesia, a separate group of animals were implanted with bilateral cannulae into the PAG and received infusions of (+)-naloxone (a stereoselective TLR4 antagonist) immediately prior to subcutaneous morphine injections. PAG TLR4 antagonism eliminated sex differences in morphine analgesia, with females responding comparably to male vehicle controls. These results suggest that sex differences in opiate activation of glia contribute to the sexually dimorphic actions of morphine, and that inhibition of PAG glia activation will facilitate morphine analgesia in females.

Title: Astrocytes are activated in the absence of microglial activation in chemotherapy-induced peripheral neuropathy models in rats

Authors: *C. R. ROBINSON, P. M. DOUGHERTY;
Pain Med., UT MD Anderson Cancer Ctr., Houston, TX

Abstract: Activation of glial cells has been shown to correlate with the development and ongoing presence of multiple chronic pain models, particularly in the context of nerve injury. While microglia are active in these injury models, they are not active in chemotherapy-induced pain models. However, it was recently shown that astrocytes are active in paclitaxel-induced peripheral neuropathy in rats. The aim of the present study was to determine whether this trend of astrocytic activation holds true in other chemotherapy models of pain. Spinal cords from male

Sprague-Dawley rats were used for all experiments. Astrocytic and microglial activation was quantified across time points corresponding to the induction, maintenance, and extinction of hyper-reflexive behavioral phenotypes in oxaliplatin, bortezomib, and chronic constriction injury (CCI) models. Additionally, glial activity was quantified at lumbar, thoracic, cervical, and midbrain levels in these models to determine whether glial activation was localized to regions corresponding to hyper-reflexive dermatomes. It was found that astrocytes were activated only at early time points following oxaliplatin treatment, but showed persistent activation following bortezomib treatment in a time course parallel to changes in behavior. Microglia were not activated at any time point in any of the chemotherapy models, but did show activation in the CCI model. Additional experiments to be presented in the poster will include a more subtle assay into the activation state of microglia in these models. In addition to staining with OX-42, additional staining will include markers to M1 and M2 activation states of microglia to determine whether there is a more subtle change in the functional state of microglia.

Abstract: Water transport via the aquaporin-4 channel (AQP4) located in the perivascular and subpial astroglial processes contributes to physiological and pathological volume changes of the extracellular space (ECS) affecting ECS ionic and osmotic balance and thus neuronal

excitability. AQP4 is anchored by α-syntrophin (α-syn), thus making α-syn deficient mice (α-syn -/-) a useful model for studying the role of AQP4 in astroglial volume homeostasis. In order to visualize and quantify morphological changes in astrocytes that lack α-syn, double transgenic mice (DT) were generated by crossbreeding GFAP/EGFP mice with α-syn -/- mice. GFAP/EGFP mice were used as a control group ("wild type" - wt). Measurements were performed in the somatosensory cortex of DT and age-matched wt mice. Astroglial volume changes were assessed by 3D-confocal morphometry, and the ECS volume fraction α (α = ECS volume/total tissue volume) and tortuosity λ (λ2 = apparent diffusion coefficient/free diffusion coefficient) were measured using the real-time iontophoretic method. Experimental models of physiological and pathological cell swelling included: 30 min superfusion of brain slices by hypotonic solution (250 and 200 mOsm) and solutions with elevated K+ (10 and 50 mM).
Control values of α were significantly smaller in wt mice (0.19 ± 0.01, N = 16, N - number of animals) than in DT animals (0.22 ± 0.01, N = 19) with no significant difference in λ. While the relative decrease after superfusion with 250 mOsm solution did not differ between wt and DT mice, the ECS shrinkage induced by 200 mOsm solution as well as by a mild increase in K+ (10 mM) was smaller in DT than in wt mice (200 mOsm : by 25 and 42 %, respectively; 10 mM K+: 23 and 35 %, respectively). 50 mM K+ induced a pronounced decrease in α by 70 % in both wt and α-syn -/- mice. Similarly, 3D-confocal morphometry revealed that α-syn deletion results in significantly smaller astrocyte swelling only when induced by more severe stress (200 mOsm or by 50 mM K+). The volume recovery of cortical astrocytes from DT mice was significantly slower following their exposure to 200 mOsm, whereas no differences between wt and DT mice were found in astrocyte volume recovery after perfusion with 50 mM K+. Our results suggest that AQP4 channels contribute to astroglial swelling and changes in the ECS volume, especially during more severe insults. These alterations may affect the concentration and diffusion of neuroactive substances and thus influence the level of tissue damage during brain edema.

Title: Stimulation-induced volume changes of the CA1 region in rat hippocampal slices

Authors: A. B. GUTWEIN[1], *J. E. OLSON[2];
[1]Dept Neuroscience, Cell Biol. and Physiol., [2]Dept Emergency Med., Wright State Univ. Boonshoft Sch. Med., Dayton, OH

Abstract: Changes in brain extracellular and intracellular volumes occur during pathophysiological conditions; however, mechanisms of cell swelling and volume regulation during functional brain activity are unclear. To examine these processes, volume changes in stratum radiatum of the CA1 region of 400 µm Sprague-Dawley rat hippocampal slices were evaluated during stimulation of Schaffer collaterals. Field potentials in the CA1 pyramidal layer were monitored to assure slice viability and evaluate drug actions. The stimulation strength of 200 µsec bipolar pulses was adjusted to the lowest current which produced the maximal field potential (0.2-0.9 mA). We characterized changes hippocampal volume by irradiating slices with white light and acquiring images every 10 sec to measure light transmission through the tissue (intrinsic optical signal or IOS). Slices were perfused with artificial cerebrospinal fluid (aCSF) and the effects of synaptic activity, ionotropic glutamate receptor (iGluR) activation, glutamate uptake, and volume regulated anion channels (VRAC) were examined by altering the aCSF composition or by adding drugs. Data were analyzed using ANOVA with Dunnett's post hoc test ($p<0.05$ indicated significance). We found IOS increased with stimulation frequency between 1 Hz and 10 Hz. Stimulation for 5 min at 10 Hz was selected for the remaining experiments because it produced consistent and significant swelling. With this stimulation frequency, IOS initially increased from baseline by 2.21 ± 0.72% per min. IOS returned to the baseline value 5 min after the stimulation train with an initial rate of recovery of -1.26 ± 0.32% per min. When synaptic activity was blocked by perfusing the slice with high Mg+2/low Ca+2 aCSF, the initial IOS rate of change with stimulation was reduced by 81% and IOS did fully recover following the stimulation train. CNQX and MK-801 (iGluR AMPA and NMDA antagonists, respectively) did not affect the initial IOS rate of change with stimulation, but did inhibit the initial IOS rate of recovery after the stimulation train by 52% and 59%, respectively. Inhibition of EAAT1 and EAAT2 mediated glutamate uptake with TFB-TBOA reduced the initial IOS rate of change with stimulation by 70%, similar to that observed with synaptic block. VRAC inhibition with niflumic acid, NPPB, and DCPIB caused various stimulation-induced changes in IOS suggesting the responses were caused by effects on components other than VRAC. We conclude the majority of swelling during stimulation is due to glutamate accumulation. Ionotropic glutamate receptors play a role in initiating volume recovery following stimulation; however, recovery is not dependent on VRAC activity.

Title: The role of astrocytic swelling on neuronal excitability: Implications for both cerebral edema and epilepsy

Authors: *K. LAUDERDALE, T. FIACCO;
Univ. of California Riverside, Riverside, CA

Abstract: Cerebral edema affects millions of people worldwide suffering from various diseases, disorders, and injuries such as stroke, cardiac arrest, epilepsy, autism, and traumatic brain injury. Edema is characterized by swelling of the brain tissue, increased intracranial pressure, reduced cerebral blood flow and can result in seizures, cerebral herniation, and death. It has been known for some time that cell swelling and reduction of the extracellular space can lead to increases in neuronal excitability and seizures in vitro and in vivo. The elevated neuronal excitability has mainly been attributed to increased ephaptic interactions between neurons. However, astrocytes may contribute actively to this process due to their selective expression of the glial water channel aquaporin 4, together with evidence that astrocyte swelling in vitro leads to significant amounts of glutamate release through astrocytic volume-regulated anion channels. Here we provide evidence suggesting that increased neuronal excitability is an active process triggered by astrocytic swelling specifically. Astrocyte swelling was evoked using a hypoosmolar ACSF solution, during simultaneous recording of activity in CA1 pyramidal neurons in acute mouse hippocampal slices in vitro. Astrocyte swelling produced the following excitatory effects in neurons: large amplitude slow inward currents (SICs), mixed excitatory postsynaptic currents (sEPSCs)/miniature EPSCs (mEPSCs), low amplitude slow inward currents (LA SICs), outward currents (OCs), and seizure-like discharges. Neuronal activity was increased during astrocytic swelling in a dose dependent manner with greater reductions in osmolarity resulting in increased neuronal excitability. Astrocytic swelling was capable of inducing neuronal firing of action potentials independent of AMPA receptor activation. Neuronal excitability was also increased during astrocytic swelling independent of neuronal action potentials and AMPA receptor activation. Taken together, these results indicate that selective astrocyte swelling in hypoosmolar conditions actively contributes to neuronal excitability by activating several different types of receptors. These findings may have important implications for the treatment of numerous conditions associated with cellular swelling and excitotoxicity including stroke, ischemia, traumatic brain injury, hyponatremia, inflammatory diseases, and epilepsy. Additional experiments are underway to determine if this astrocytic pathway contributes forms of epileptiform activity including interictal and ictal discharges, status epilepticus and spontaneously recurring seizures.

Title: Seizures and swelling: What role does astrocyte volume change play in high [K+]o-induced epileptiform activity?

Authors: *T. R. MURPHY, T. A. FIACCO;
Cell Biol. and Neurosci., Univ. of California, Riverside, Riverside, CA

Abstract: Epilepsy, a neurological disorder characterized by recurrent seizures, affects nearly 3 million Americans alone and nearly 500 new cases are diagnosed each day. Of these cases, two-thirds have an unknown cause, and over 40% cannot be controlled with current therapies (http://www.cureepilepsy.org). Neurologically, these seizures are the result of global hyperexcitability in CNS neurons. However, the cellular and molecular causes of this hyperexcitability are multifactorial and not well understood. Astrocytes have the ability to respond to synaptic neurotransmitters (Porter and McCarthy 1996) and release neurotransmitters under certain conditions. One such condition is through direct cell swelling during which astrocytes can regulate their volume through the opening of volume-sensitive anion channels (VRACs) that are permeable to amino acid transmitters including glutamate (Rutledge et al 1998). We hypothesize that astrocyte swelling and subsequent glutamate release contribute to the initiation and/or maintenance of the hypersynchronous discharges that underlie seizures. Utilizing a high $[K+]_o$ model of seizure-like activity in vitro, we have established a $[K+]_o$ threshold capable of initiating large, repetitive NMDA-dependent currents in hippocampal CA1 neurons. These currents appear to be the voltage-clamp correlate of paroxysmal depolarization shifts (PDSs) recorded extracellularly in other studies (forming the "interictal" part of a seizure). These discharges occur in the presence of the AMPA receptor antagonist NBQX but are blocked entirely by the NMDAR antagonist AP5. The PDSs appear sensitive to astrocytic VRAC activation, as the astrocyte-specific VRAC inhibitor DCPIB reduces them over time. To further investigate the role of astrocytic swelling-activated glutamate release, we plan to selectively block astrocyte swelling via "volume-clamp" using a patch pipette, and also to directly image astrocyte swelling in high $[K+]_o$ via confocal imaging. Directly loading astrocytes with high levels of glutamate, and recording the result on epileptiform currents will also provide a direct connection between astrocytes and PDSs. Future work will examine changes in threshold or severity of epileptiform activity induced in control versus seizure-prone mice. Additionally, we

plan on developing a model of the “ictal” portion of a seizure, a crucial part of understanding the astrocytes’ role in the development of epilepsy.

Title: Glial aquaporin-4 water channels in substantia nigra: Implications for parkinson's disease

Authors: K. STAHL[1], A. PRYDZ[1], M. NADEEM[1], N. DAVARPANEH[1], *M. AMIRY-MOGHADDAM[2];
[1]Lab. of Mol. Neuroscience, Dept Anat,, [2]Dept Anat, CMBN, Univ. Oslo, Inst. Basic Med. Sci., Oslo, Norway

Abstract: Aquaporin-4 (AQP4) is the predominant water channel in the brain. Here, it is selectively expressed in astrocyte endfeet facing microvessels, in a highly polarized manner. The polarized expression of AQP4 in astrocytes is crucial for homeostatic processes maintaining normal neuronal function, including water and potassium homeostasis. We have previously shown that loss of AQP4 polarity is associated with several neurological conditions, including stroke, epilepsy and neurodegenerative diseases, such as Alzheimer’s disease. The role of AQP4 in Parkinson’s disease (PD), however, remains largely unexplored. In this study, we aim to investigate the distribution and function of AQP4 in normal substantia nigra (SN) and in animal models of PD.
The distribution of AQP4 in the SN is compared to the cerebral cortex in normal C57BL/6 mice, and in a mouse model of PD, where 1-methyl-4-phenylpyridinium (MPP+) is injected intrastriatally and kept for 7 days in vivo. All animals are perfusion fixed and brains are analyzed using and confocal immunofluorescence and quantitative immunogold electron microscopy. When characterizing the expression of AQP4 under normal conditions, we find significantly higher levels of AQP4 in the SN, as compared to the cerebral cortex. The abundant AQP4 expression is highly polarized around perivascular processes, and there is also substantially more AQP4 in astrocyte processes throughout the neuropil, compared to the cerebral cortex. The high density and polarized expression of AQP4 around perivascular endfeet and processes in the neuropil suggest that AQP4 might play an important role for maintenance of neuronal function in

the SN. We are currently investigating expression patterns of AQP4 in animal models of PD to study its potential role in the PD pathophysiology.

Title: NMO sera down-regulate the expression of aqp4 in human astrocyte and induce cytotoxicity independent of complement

Authors: *H. HARUKI[1,2], Y. SANO[2], F. SHIMIZU[2], M. OMOTO[2], A. TASAKI[2], M. OISHI[2], M. KOGA[2], T. FUKUSAKO[1], T. KANDA[2];
[1]Dept. of Neurology, Yamaguchi Grand Med. Ctr., Houhu/Yamaguchi, Japan; [2]Dept. of Neurol. and Clin. Neurosci., Yamaguchi Univ. Grad. Sch. of Med., Ube, Japan

Abstract: Background: Autoantibodies against astrocyte water channel aquaporin-4 (AQP4) are highly specific for neuromyelitis optica (NMO). However, to date, the molecular mechanism of NMO is unclear. Although AQP4 exists as two different heterotetramers, M-1 and M-23 AQP4, which result from usage of different start codons and vary in the 23 amino acids in the N terminus of the protein, *in vitro* study using human astrocyte, particularly the cells expressing dominantly M23 isoform, is rare. The purpose of this study was to identify the possible humoral mechanisms responsible for the astrocytic damage.
Methods: Human primary astrocyte (AST) was immortalized by retroviral vectors harboring temperature-sensitive SV40 T antigen gene and AQP4 cDNA (M23), designated as hAST-AQP4. This line was used to determine whether NMO sera influence the amount of AQP4, excitatory amino acid transporter 2 (EAAT2) as construct AQP4-associated protein-complexes and inflammatory cytokines. In addition, the effects of NMO sera on the morphology and viability of astrocytes and the subcellular localization of AQP4 were investigated.
Results: After exposure of NMO sera, hAST-AQP4 exhibited extension of narrow processes and surface membrane-bound AQP4 proteins were gathered and appeared punctate, dot-like structures. NMO sera alone induced cytotoxicity and addition of complement had more harmful effect on hAST-AQP4. NMO sera decreased AQP4 mRNA and protein. The amount of EAAT2

in the human astrocytes was significantly decreased following exposure to NMO sera. NMO sera alone up-regulated TNFα and IL-6 in astrocytes and co-incubation with anti-TNFα and anti-IL-6 neutralizing antibodies blocked both the cytotoxicity and reduction of AQP4 in astrocytes. **Conclusions:** NMO sera solely could bring cytotoxicity on human astrocyte, involving AQP4 reduction and inflammatory cytokine up-regulation. The future elucidation of factors that block the production of inflammatory cytokines may therefore lead to the development of a novel therapeutic strategy.

Title: Targeting inflammasome activation is a promising strategy to control seizures induction and recurrence

Authors: *L. LIBRIZZI, F. M. NOÈ, M. DE CURTIS;
Dept of Exptl. Neurofisiology and Epilettology, Fondazione Inst. Neurologico C. Besta, Milan, Italy

Abstract: Associated brain inflammatory response occur in human focal epilepsies and promote the generation of seizures in experimental models. Pro-inflammatory mediator interleukin (IL)-1beta contribute to seizure generation, and pharmacological blockade of its cognate receptor IL-1R1 reduces experimental seizures [Vezzani, Brain Behaviour & Immunity 25:1281,2011; Vezzani, Nat Rev Neurol 7:31,2011; Librizzi, Ann Neurol xx 2012]. IL-1b biosynthesis and release is pivotally controlled by the assembly of a macromolecular complex called NLRP3 inflammasome, consisting of regulatory, adaptor and effector subunits (Schroder & Tschopp, Cell 140:821,2010). ATP released during seizures, activates the NLRP3 inflammasome by stimulating the ionotropic P2X7 purinergic receptor [Mariathasan, Nature 9:228,2006]. ATP-mediated P2X7 receptor activation results opening of Pannexin-1 pore, thus leading to K efflux and intracellular Ca rise. In the present study we investigated if seizure-induced brain born inflammation and BBB damage are counteracted by a cocktail of P2X7 receptor/ Pannexin-1 complex inhibitors.

Epileptiform activity was induced by arterial perfusion with either the GABAA receptor antagonist bicuculline, or the potassium channel blocker 4-aminopyridine (4AP).
Brief application of bicuculline (50µM) consistently induced focal ictal discharge in the limbic region, as verified by simultaneous electrophysiological recordings of extracellular activity in medial entorhinal cortex (mERC) and CA1.
Arterial application of 4AP (50 µM) induced independent seizure like activities in both the olfactory region and the limbic region characterized by fast activity at onset followed by irregular spiking and rhythmic bursting (Carriero et al., 2010). In the piryform cortex (PC), we observed runs of fast activity (fast runs, FRs) that progressively became more robust and ultimately generated all-or-none seizure-like events (SLE).
The 30-min infusion via the resident arterial system of the P2X7 receptor/ Pannexin-1 complex inhibitors (A438079 100µM and Probenecid 1mM, respectively) initiated from 5 min before bicuculline or 4AP application, drastically counteract epileptiform discharges in mERC and totally abolished the FRs and SLE described in the PC.
This set of evidence suggests that NLRP3 inflammasome system may be critically involved in aberrant neuronal excitability and seizures, and its selective antagonism, through the upstream inhibition of the P2X7receptors/pannexin 1 complex, may be a promising strategy to control seizures in focal epilepsies.

Title: Complement inhibitor protein cd59 modulates cytotoxicity and inflammation in neuromyelitis optica

Authors: *H. ZHANG, A. S. VERKMAN;
Dept of Med., UCSF, SAN FRANCISCO, CA

Abstract: Neuromyelitis optica (NMO) is an autoimmune disorder or the central nervous system in which inflammatory demyelinating lesions damage spinal cord and optic nerve, and, to a lesser extent, brain. NMO pathogenesis involves binding of immunoglobulin G anti-aquaporin-4 autoantibodies (NMO-IgG) to astrocytes, causing complement-dependent cytotoxicity (CDC) and secondary inflammation, demyelination and neuron loss. Based on the central role of

complement in NMO, we investigated the involvement of the major astrocyte complement inhibitor CD59, a phosphoinositol-linked glycoprotein that inhibits the terminal C5b-9 membrane attack complex. Immunofluorescence showed strong CD59 expression at sites of aquaporin-4 expression in spinal cord, optic nerve and brain, as well as in peripheral organs including kidney. CD59 inhibition by a neutralizing monoclonal antibody greatly increased NMO-IgG-dependent CDC in primary murine astrocyte cultures, and greatly increased NMO pathology in ex vivo spinal cord slice cultures exposed to NMO-IgG and complement, causing marked demyelination. Greatly increased NMO pathology was also found in spinal cord slice cultures from CD59 knockout mice and in vivo following intracerebral injection of NMO-IgG and human complement. We found that intrathecal injection (at L5-L6) of small amounts NMO-IgG and complement in CD59-deficient mice produced robust, longitudinally extensive white matter lesions throughout the thoracic and lumbar spinal cord segments of spinal cord, whereas minimal pathology was seen in wild type mice. The lesions were most severe at 2 days after injection, showing loss of AQP4 and GFAP, demyelination, activation of microglia, infiltration of leukocytes, and remarkable loss of pain nociception in hindpaws. Our results implicate CD59 as an important modulator of the immune response in NMO, and provide a novel animal model of NMO that closely recapitulates human NMO pathology. Upregulation of CD59 on astrocytes may have therapeutic benefit in NMO.

Abstract: Inflammatory insult-induced astrocyte reactivation plays important roles in the inflammation and injury repair after brain injuries. Previous studies have shown that kynurenine (Kyn) and kynurenic acid (KyA) are detected in the blood of post-stroke patients, which points to

the possible activation of their synthesizing enzyme indoleamine 2,3-dioxygenase (IDO). IDO catalyzes the biosynthesis of Kyn from L-tryptophan, and this metabolic pathway has immune modulatory effect on peripheral immune responses. IDO is inducible by proinflammatory insults such as bacterial endotoxin lipopolysaccharide (LPS), and has been implicated in the pathogenesis of neurodegeneration. Recent studies have identified that Kyn and KyA are the endogenous ligand of the aryl hydrocarbon receptor (AhR), also known as the receptor for the environmental hormone dioxin. AhR plays important roles in immune regulation, but whether it is involved in the IDO-mediated immune modulation in CNS remains unknown. In this study, we investigated the role of AhR in the IDO/Kyn pathway and proinflammatory cytokine expression in LPS-induced astrocyte reactivation. Immunofluorescent double labeling indicated that intracerebroventricular administration of LPS induced the expression of AhR and IDO in rat brains. Western blotting and RT-PCR results also showed that both AhR and IDO were induced by LPS in cultured astrocytes, and AhR knockdown profoundly enhanced the LPS-induced IDO expression. *In vivo* study further indicated that LPS-induced IDO expression was higher in AhR-deficient mice compared with the heterozygous and wild type mice. Furthermore, LPS treatment can activate AhR accompanied by the elevation of endogenous Kyn production, and exogenous Kyn application can activate AhR. As a result, the LPS-induced proinflammatory cytokine IL-6/TNFalpha expression was found negatively regulated by the LPS-induced AhR and IDO expression. In contrast, LPS-induced astrocyte hypertrophy was attenuated by AhR knockdown. Together, our data suggest that LPS-induced astrogliosis involves the activation of IDO to synthesize AhR ligand Kyn, which in turn activates AhR to negatively feedback the LPS-induced IDO and proinflammatory expression in order to control the astrocyte-mediated neuroinflammation.

Title: Induction of Krüppel-like factor 4 expression in reactive astrocytes following ischemic injury *In vitro* and *In vivo*

Authors: PARK, T.-R. RIEW, Y.-J. SHIN, J.-M. PARK, J. CHO, M.-Y. LEE;
Dept. of Anat., Dept. of Anatomy, Col. of Medicine, The Catholic Univ. of Korea, Seoul/seocho-Gu, Korea, Republic of

Abstract: Krüppel-like factor 4 (KLF4) is a transcription factor with diverse and cell-type specific functions and is linked to a variety of pathophysiological processes. Recently, it has been proposed that regulation of KLF4 is critical to neuronal differentiation and that neural progenitors with KLF4 overexpression form cells with a glial identity. The present study was designed to determine whether KLF4 is involved in astroglial reaction induced by ischemia-reperfusion injury in brain. Astroglial reaction characterized by glial fibrillary acidic protein upregulation and astrogliosis participates in the pathogenesis of neurological disorders. No specific KLF4 immunoreactivity was expressed in resting astrocytes of the control hippocampus, but significant induction was detected in reactive astrocytes preferentially located in the CA1 and dentate hilar regions of the hippocampus following transient forebrain ischemia. Astrogial KLF4 expression was induced in their nuclei and cytoplasm within three days after ischemia, and maintained for at least four weeks. This pattern is reproduced in *in vitro* astrogliosis model of rat primary cortical astrocytes exposed to oxygen-glucose deprivation (OGD). Further, immunoblot assay showed that nuclear and cytosolic extracts from cortical astrocytes subjected to OGD displayed a significant increase of KLF4 protein compared with normoxic extracts. Thus, our data demonstrated that KLF4 expression was induced in astroglia becoming reactive elicited by ischemic injury in vivo and in vitro, suggesting that KLF4 may act as a transcription factor linked to the regulation of the astroglial reaction after ischemic injury.

Science, Ctr. for Neurosci., Tohoku Univ. Grad. Sch. of Med., Sendai, Japan

Abstract: The brain demands high-energy supply and obstruction of blood flow causes rapid deterioration of the healthiness of brain cells. Two major events occur upon ischemia; acidosis and glutamate excitotoxicity. Aerobic metabolism shuts down as a consequence of oxygen and glucose deprivation; however, lactate production from glycogen stored predominantly in glial cells continues, which leads to severe acidosis. Neuronal cell death via glutamate excitotoxicity follows; however, cellular source of glutamate and mechanism of its release remain uncertain. Here we show a causal relationship between glial acidosis and neuronal excitotoxicity. As the major cation that flows through channelrhodopsin-2 (ChR2) is proton, this could be regarded as an optogenetic tool for instant intracellular acidification. Optical activation of ChR2 expressed in cerebellar glial cells led to glial acidification and to activation of glutamate receptors on Purkinje cells in acute brain slices. Depolarization alone by local application of potassium was insufficient to cause glial glutamate release and intracellular calcium chelation did not stop glutamate release caused by the glial ChR2 activation. On the other hand, glial alkalization via optogenetic activation of a proton pump, archaerhodopsin (ArchT), led to cessation of glutamate response in Purkinje cells during oxygen/glucose deprivation in acute slices and to relief of ischemic brain damage in vivo. Our results suggest that glial acidification is a key trigger for glutamate release from glia upon ischemia and, thus, devising a way to control glial pH may be an effective therapeutic strategy for relieving ischemic neuronal cell death.

Abstract:
Astrocyte activation is associated with acute injury and found in nearly every chronic neurodegenerative disease. Nevertheless, the impact of activated astrocytes on neurologic function remains poorly understood. The activated astrocyte phenotype appears to be regulated, in part, by the protein phosphatase calcineurin (CN) and the CN-dependent transcription factor, NFAT. Consistent with previous work on primary neural culture models, we recently showed that selective inhibition of astrocytic CN/NFAT signaling using adeno-associated virus (AAV) vectors suppressed morphologic features of astrocyte activation in an intact mouse model of Alzheimer's disease (AD). Importantly, these changes were associated with reduced microglial activation, reduced Abeta pathology, and improved cognitive and synaptic function. The results suggest that activated astrocytes, in general, and astrocytic CN/NFAT activity, in particular, negatively regulate neurologic function under some degenerative conditions. In the present study, we determined the extent to which astrocytic CN/NFAT activity contributes to functional outcome in a rat model of cortical contusion injury (CCI). Adult rats received bi-lateral hippocampal injections of AAV vectors expressing the human GFAP promoter (Gfa2) and the potent CN/NFAT inhibitor, VIVIT. At 2-3 months post-infection, rats received a unilateral CCI and were permitted to recover for one week. Hippocampal slices were then prepared from injured and uninjured hemispheres for the electrophysiologic assessment of CA3-CA1 synaptic strength and susceptibility to long-term depression (LTD) obtained under investigator-blind conditions. Relative to slices from the uninjured hemisphere and slices from sham animals, slices from the injured hemisphere of control rats (i.e. rats treated with a control AAV construct--AAV-Gfa2-EGFP) exhibited significantly reduced basal synaptic strength and robust LTD. In contrast, synaptic strength in rats treated with AAV-Gfa2-VIVIT was very comparable across the injured and uninjured hemispheres and nearly indistinguishable from sham rat slices. Moreover, slices from AAV-Gfa2-VIVIT rats showed almost no LTD. Finally, AAV-Gfa2-VIVIT provided significant protection from the loss of GluR1 receptors characteristic of injured hippocampal tissue of control rats. Thus, similar to results with AD mouse models, activated astrocytes appear to contribute to synaptic dysfunction in a model of acute traumatic brain injury. Ongoing studies

are determining the extent to which astrocytic CN/NFAT activity regulates neuroinflammatory markers following CCI.

Title: Synaptogenic effects of astrocytic ephrinB1 in the adult mouse hippocampus following severe traumatic brain injury

Authors: *A. M. NIKOLAKOPOULOU[1], J. LEISH[1], S. MORTAZAVI[1], A. OBENAUS[2], I. M. ETHELL[1];
[1]Biomed. Sci., Univ. of California Riverside, Riverside, CA; [2]Pediatrics, Loma Linda Univ., Loma Linda, CA

Abstract: Molecular and cellular mechanisms of neuron-glial interactions that regulate brain repair following traumatic brain injury (TBI) have attracted the attention of many investigators. EphrinB1 was identified as one of the genes that are upregulated in reactive astrocytes and may promote or hinder regeneration of brain circuits after brain injury. Here, we focus our studies on the involvement of ephrinB1/EphB2 receptor signaling in reactive synaptogenesis and brain repair following TBI. We tested ephrinB1 expression in mouse hippocampi at 1, 3 and 7 days post TBI using a controlled cortical impact model and observed a significant increase in ephrinB1 protein levels in hippocampal astrocytes at 3 days post-TBI. Astrocytic upregulation of ephrinB1 was mostly noted in the stratum radiatum (SR), whilst the hilus of the dentate gyrus showed a moderate increase in the number of GFAP positive astrocytes and ephrinB1-expressing cells. Upregulation of ephrinB1 levels at 3 days post TBI was followed by a significant downregulation of astrocytic ephrinB1 at 7 days post TBI that coincided with a peak of reactive astrogliosis. We have also found a significant downregulation in the number of glutamatergic synapses in SR at 3 days post TBI in both injured and non-injured hemisphere. Interestingly, we

see up-regulation of ephrinB1 in neurons, but not astrocytes, in the cortex suggesting that astrocytic upregulation of ephrinB1 is specific to the hippocampus. We have also examined GFAP, vimentin (markers for reactive astrocytes), ephrinB1 and EphB2 mRNA expression following TBI and our results show an increase in gene expression following TBI. We are currently investigating the effects of specific ephrinB1 ablation in astrocytes on synaptic rewiring following TBI in the hippocampus of conditional ephrinB1 knockout mice. Our data show that Cre-induced ablation of ephrinB1 in astrocytes increased the number of glutamatergic synapses 3 days post TBI thus implying that ephrinB1 may play a role in trimming excitatory connections following TBI as a protective mechanism against excitotoxicity. Our in vitro studies support this possibility and show that addition of ephrinB1-expressing, but not ephrinB1-deficient, astrocytes to developed neuronal cultures triggers a significant increase in the number of synapses. Our studies suggest that ephrinB1 may play a neuroprotective role in the brain by modulating synaptic connectivity following TBI.

Title: Temporal patterns of the embryonic intermediate filament nestin in the hippocampus of mice after TMT treatment

Authors: *S. LEE, J. KIM, J. KIM, Y. SON, S.-H. KIM, J.-C. KIM, T. SHIN, C. MOON; Buk-gu, Chonnam Natl. Univ., Gwangju, Korea, Republic of

Abstract:
Nestin is an embryonic intermediate filament protein that is expressed in multipotent neural stem cells of the central nervous system. In this study, the expression pattern of nestin in the mouse hippocampus 1, 2, 4 and 8 days after trimethyltin (TMT) treatment was examined to elucidate its role in the chemical-induced hippocampal injury. The mRNA level of nestin was significantly increased in the hippocampus 2 days post-treatment, and thereafter, decreased 4 and 8 days post-treatment. The protein level of nestin was significantly increased 4

days post-treatment, and the expression was localized predominantly in GFAP-positive astrocytes in the hippocampal dentate gyrus and CA3. Therefore, we suggest that nestin contributes to the remodeling of the chemically injured region in the hippocampus, possibly through the activated cell migration and the glial scar formation.

Title: Amygdala astrocytic responses to corticotropin-releasing factor and stress

Authors: *L. H. CONTI[1,2], L. M. O'KEEFE[3], S. MACISAAC[3], S. J. CROCKER[3];
[1]Med. Sci., Quinnipiac Univ., Hamden, CT; [2]Psychiatry, [3]Neurosci., Univ. of Connecticut Hlth. Ctr., Farmington, CT

Abstract: Astrocytes are known to play a role in synaptic transmission and along with pre- and post-synaptic neurons form tripartite synapses (Allen and Barres, 2009). The effect of stress on astrocyte function has been studied with mixed results. However, the results of most studies show that astrocytes are activated by stress. The neuropeptide, corticotropin-releasing factor (CRF) is released during stress with behavioral consequences. Both CRF_1 and CRF_2 receptors are found on astrocytes, suggesting the possibility that CRF would have a functional effect on astrocytes in an *in vivo* model. To examine this, Brown Norway rats received either an intracerebroventricular (ICV) infusion of CRF (1.0 μg in 5.0μl) or saline, and brains were harvested 90 min later. To assess astrocyte activation, we examined GFAP immunoreactivity in the basolateral nucleus of the amygdala (BLA). We found that rats which received an ICV infusion of CRF had a significantly greater number of GFAP-positive cells in the BLA than vehicle-treated rats. In a second experiment, rats were either naïve, or underwent 90 min of restraint stress and brains were harvested either immediately, or 24 hr after the termination of restraint. We found a significantly greater number of GFAP-positive cells in the BLA of rats sacrificed 24 hr after stress termination than in either the naïve group or the group that was sacrificed immediately after restraint. Finally, we found that application of CRF to primary astrocyte cultures specifically activated the p38 kinase pathway and enhanced EIF-4E expression

levels. Together, these results implicate astrocytes in the cellular responses to CRF and stress, suggesting that astrocytes may participate in the behavioral responses to CRF and stress.

Title: Astrocyte activation in pre-pubescent rats stressed by chronic environmental noise

Authors: *O. HUET[1], Y. RUVALCABA-DELGADILLO[1], R. GONZÁLEZ-CASTAÑEDA[1], J. GARCÍA-ESTRADA[2], A. FERIA-VELASCO[1], M. MACÍAS-ISLAS[2], S. LUQUIN[1];
[1]Univ. De Guadalajara, Zapopan, Mexico; [2]IMSS, Guadalajara, Mexico

Abstract: Chronic urban noise can be a deleterious stimulus for those who do not habituate to it, with subsequent adverse health effects. Pre-pubescent individuals who are exposed to this phenomenon go through a critical period in which stressors can alter brain development and long term neurological processes. We previously showed that our noise model works as a moderate stressor which stimulated spatial learning abilities in both, young and adult rats. The aim in the current study was to analyze if astrocytes; cells that regulate neuron function in many ways, and get activated in many central nervous system pathologies, modified their morphology after exposure to chronic environmental noise. Ten recently weaned male Wistar rats were subjected to noise (urban sounds adapted to the rat audiogram) during 15 days, from 21-36 postnatal days. Then, Glial fibrillary acidic protein (GFAP) was analyzed by immunohistochemistry in CA1, CA3 and dentate gyrus regions of hippocampus. The results shown a non-significant increase in the number of GFAP immunopositive cells in all regions, Scholl analysis demonstrated a significant increase in the length of the astrocyte processes of rats exposed to noise. These findings suggest that noise as a moderate stressor can promote learning abilities after astrocyte activation. It may be that astrogliosis has a role in the process of learning under moderate stress.

Title: Expression of the mRNA of the α isoforms of the sodium pump in cerebellum of rats with nutritional stress

Authors: *R. MERCADO[1], G. NAVA[2], R. ESQUIVEL[2], C. S. BAUTISTA[2], O. A. SIFUENTES[2], O. GUZMÁN[2], F. BOLAÑOS[3];
[1]U.M.S.N.H., Tarimbaro, Michoacan, Mexico; [2]U.M.S.N.H., Morelia, Michoacan, Mexico; [3]INRA-UNIVERSITE DE NANTES, NANTES, France

Abstract: The sodium and potassium pump (Na^+/K^+-ATPase) is an enzymatic complex which is located in the plasmatic membrane of all animal , it is constituted by two α subunits, of which there are 4 isoforms (α1, α2, α3 y α4) and 2 β subunits of which are known 3 isoforms (β1, β2 y β3), this enzyme regulates the Na^+ and K^+ ions concentration, it maintains the cellular volume and resets the membrane potential among
others. One the other hand, it is know that serotonin (5-hidroxitryptamine, 5-HT) increase the Na^+/K^+-ATPase activity of glial cells in the cerebellum of rats, and it has been observed an increase in the Vmax of
the enzyme kinetics induced by serotonin and an increase in the ouabain binding to the sodium and potassium pump has been observed in rats' cerebellum with protein-caloric restriction (PCR). Serotonin it is synthesized from the essential amino acid L-tryptophan. Experimentally its synthesis can be activated by administering its precursor or schemes of fetal protein-caloric restrictions. The mechanisms involved in the increase of sodium pump activity by 5-HT is unknown, so, the objective of the present work was to explore using RT-PCR techniques the expression of α isoforms of the enzyme in the cerebellum of
rats with protein-caloric restriction and rats administered with L-Trp. The results showed that in the cerebellum of rats with RPC the expression of mRNA of the a2 subunit was increased in 24.7 % and the enzymatic activity was increased 18.2%. In the cerebellum of rats administered with L-tryptophan the expression of the α2 isoform was increased in 70% and the enzymatic activity was increased in 46.6%. In relationship with the other α isoforms (α1 and α2) they did not show changes in their expression in any group compared with the control group. This data suggest that the 5-HT increase the activity of sodium and potassium pump through the increase of expression

of the α2 catalytic subunit in cerebellum of rats with nutritional stress. This work was partially supported by: U.M.S.N.H.- CIC 26.2 (2013), ANUIES-SEP-CONACyT-ECOS NORD.

Title: Mechanisms underlying Roundup®-induced neurotoxicity in immature rat hippocampus

Authors: *A. ZAMONER PACHECO DE SOUZA, D. CATTANI, V. L. L. O. CAVALLI, J. T. DOMINGUES, C. E. H. RIEG, C. M. ANDRADE, T. DAL-CIM, C. I. TASCA, F. R. M. B. SILVA;
Bioquímica, Univ. Federal De Santa Catarina, Florianópolis, Brazil

Abstract: Glyphosate is the primary active ingredient present in the herbicide Roundup® and is the widely used herbicide worldwide. The present results show that the herbicide Roundup® induces glutamatergic excitotoxicity, oxidative stress and activates multiple signaling pathways leading to neural cell death in rat hippocampus. The pesticide causes Ca^{2+} overload by activating NMDA receptors and L-type voltage-dependent Ca^{2+} channels (L-VDCC) setting off oxidative stress and cell death. The mechanisms underlying Roundup® neurotoxicity involve the activation of Ca^{2+}/calmodulin-dependent protein kinase II (CaMKII) and extracellular signal-regulated kinase (ERK). Astrocytes play a key role in removing glutamate from the synaptic cleft and metabolizing it to glutamine, which serve as a glutamate precursor in neurons. Our results demonstrated that Roundup® reduced glutamate uptake and metabolism within glial cells, associated with increased release of this neurotransmitter in the synaptic cleft. Moreover,

Roundup® leads to glutamine synthetase, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) enzymatic activity inhibition, attesting that either glutamate uptake or its metabolism is impaired in hippocampal astrocytes exposed to the herbicide. Moreover, Roundup® reduced GSH levels and increased the amounts of thiobarbituric acid reactive species (TBARS), characterizing oxidative damage. Also, exposure to the pesticide decreased the activity of gamma-glutamyl transferase (GGT) and glucose-6-phosphate dehydrogenase, supporting the depletion of GSH. In this context, the GGT inhibition induced by Roundup® could decrease the amino acid availability to GSH *de novo* synthesis and the decreased activity of G6PD may reduce NADPH levels, necessary to reduce glutathione. Taken together these results demonstrated that Roundup® might lead to excessive extracellular glutamate levels and consequently to excitotoxic condition and energetic deficit in rat hippocampus.

Title: Connexin43 phosphorylation impacts neuroprotection

Authors: *C. C. NAUS[1], M. FREITAS-ANDRADE[1], J. BECHBERGER[1], B. MACVICAR[2], P. LAMPE[3];
[1]Dept of Cell. & Physiological Sci., [2]Brain Res. Centre, Dept of Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada; [3]Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract: One of the major ways astrocytes communicate is via gap junctions, unique membrane channels that allow for intercellular and extracellular signaling. Gap junctions are composed primarily of connexin43 (Cx43), a gap junction protein which has been shown to be both beneficial and detrimental in different models of neurotoxicity. With regard to models of ischemia, several reports have demonstrated that Cx43 is an important factor in neuroprotection, however the molecular mechanisms are unclear.

The transmembrane regions of Cx43 are relatively conserved with other connexins, however, the cytoplasmic region is divergent and has been shown to be critical for the regulation of channel and hemichannel activity. The Cx43 C-terminus has been the focus of significant analysis, with putative phosphorylation sites identified using kinases that directly mediate channel gating properties. We have used transgenic mice with mutated phosphorylation sites in a middle cerebral artery stroke model. To examine the role of phosphorylation in neuroprotection, we have used mice with mutations that include the protein kinase C (PKC) site Cx43(S368A), the Casein kinase 1 (CK1) site Cx43(S325A/328Y/330A), and the mitogen activated protein kinase (MAPK) site Cx43(S255/262/279/282A). After 4 days of recovery, brain sections were histologically evaluated for infarct volume. Immunofluorescent analysis of astrocyte reactivity, microglial activation, Cx43 expression, vascular elements and apoptosis were also performed. While we did not observe a significant difference in infarct volume comparing wild type mice to the CK1 transgenic mice, we noted a non-significant increase in PKC mice. More importantly, a significant decrease in infarct volume was measured in MAPK mice. In the penumbra, an increase in astrocyte reactivity was observed in the MAPK mice, compared with wild type mice. Consistent with the infarct volume data, a significant reduction in cell death was also observed in MAPK mice. These results suggests that specifically inhibiting MAPK phosphorylation of Cx43 provides neuroprotection in ischemic conditions, while preventing PKC and CK1 phosphorylation show no protective effect.

Title: Deimination as an astrocytic marker following temperature incubation

Authors: *M. E. ALGECIRAS[1], H. M. SERRA[2], S. K. BHATTACHARYA[1];
[1]Ophthalmology, Univ. of Miami, Miami, FL; [2]Univ. Nacional de Cordoba, Cordoba, Argentina

Abstract: Purpose: To determine whether temperature fluctuation elicits an increase in deimination (conversion of protein bound arginine into citrulline) in astrocytes and whether elevated deimination levels can serve as an astrocytic activation marker. Astrocyte activation will be assessed by measuring the expression of a repertoire of established astrocytic markers, including GFAP.
Methods: Isolated brain cortex astrocytes obtained from C57BL/6J mice (about 5000 per plate) were cultured and subjected to different incubation temperatures for one hour, followed by a stabilization period of 23 hours at 37°C. The exposed and control astrocytes were evaluated for deimination levels as well as for levels of other established markers of astrocyte activation using immunohistochemical, Western blot and ELISA analyses.
Results: Optimal growth of astrocytes occurred at 37°C. Hypothermia (31°) treatment showed very few loss of cells (2%) as measured by Tunnel assay. However, 33% cell death was found after hyperthermic incubation (41°) for 1 hour. Decreased GFAP, deimination and peptidylarginine deiminase type 2 (PAD2) levels were found in cells subjected to hypothermia. An increase in some astrocyte activation markers such as Aquaporin4, S100β and Thrombospondin, however, was found in astrocytes subjected to hypothermia. The astrocytes subjected to hyperthermia showed an increase in deimination and PAD2 levels. Furthermore their levels were higher (approximately 3-fold) than for the cells subjected to hypothermia. Hyperthermia was accompanied by an increase in some astrocytic markers such as GFAP, aldehyde dehydrogenase 1 family member L1 (ALDH1L1), J131 and isolevuglandin (ISO[4]LGE2). Mass spectrometric analysis revealed some unique proteins associated with each treatment condition.
Conclusion: The level of deimination undergoes a shift on either side of optimal temperature incubation (37°C) for astrocytic growth. Level of deimination correlates with astrocyte activation markers when cells are subjected to temperature treatment.

Title: Gαh/TG2 promotes cAMP production accompanied by a modification of adenylylcyclase 8 in human and rat glioma cells

Authors: *Y. OBARA[1,2], Y. YANAGIHATA[2], T. ABE[2], L. DAFIK[3], K. ISHII[1], N. NAKAHATA[2];
[1]Pharmacol., Yamagata Univ., Yamagata-Shi, Japan; [2]Tohoku Univ., Sendai, Japan; [3]Stanford Univ., Stanford, CA

Abstract: Gαh (or transglutaminase-2 (TG2)) is an atypical guanine nucleotide binding-protein that associates with some G protein-coupled receptors including α1-adrenergic receptor, thromboxane A2 receptor, oxytocin receptor and follicle-stimulating hormone receptor. Gαh/TG2 also exerts transglutaminase activity that catalyzes posttranslational protein cross-linking with the formation of ε-(γ-glutamyl) lysine or (γ-glutamyl) polyamine bonds. However, the function of Gαh/TG2 in glial cells remains unclear, we therefore examined the role in signal transduction in detail. In 1321N1 human astrocytoma cells that do not express endogenous Gαh/TG2, overexpression of Gαh/TG2 caused an enhancement of cAMP accumulation stimulated with the β-adrenergic receptor agonist, isoproterenol, or the adenylylcyclase activator, forskolin. This cAMP-enhancement was reversed by the TG2 inhibitor, ERW1069 (Quinolin-3-ylmethyl(S)-1-(((S)-3-Bromo-4,5-dihydroisoxazol-5-yl)methylamino)-3-(5-fluoro-1H-indol-3-yl)-1-oxopropan-2-ylcarbamate). In rat C6 glioma cells that express endogenous Gαh/TG2, cAMP accumulation induced by isoproterenol or forskolin was significantly inhibited by overexpression of Gαh/TG2-C277V, a dominant-negative mutant that lacks transglutaminase activity, but was not inhibited by the Gαh/TG2-S171E mutant that cannot bind GTP/GDP. These results suggest Gαh/TG2 potentiates adenylylcyclase activity by its transglutaminase activity and not by its G-protein activity. We previously showed that cAMP promoted gene expression of interleukin-6 via cAMP response element in 1321N1 cells (Obara et al., Mol. Pharmacol. 68, 1466-1474, 2005), Gαh/TG2 consistently increased the activities of the cAMP response element and interleukin-6 promoter, accompanied by an enhancement of cAMP in both glioma cells. Since a calmodulin inhibitor, W7, blocked the effect of Gαh/TG2 on cAMP accumulation and calmodulin-sensitive adenylylcyclase 8 mRNA and protein are expressed in both 1321N1 and C6 cells, we focused on post-translational modification of adenylylcyclase 8 by Gαh/TG2. Gαh/TG2 affected neither adenylylcyclase 8 expression levels, glycosylation, nor dimerization status. In contrast, Gαh/TG2 was co-precipitated with adenylylcyclase 8 and pentylamine, a substrate of Gαh/TG2, was incorporated into adenylylcyclase 8 in a transglutaminase activity-dependent manner. Taking these results together, Gαh/TG2 promotes cAMP production accompanied by a modification of adenylylcyclase 8 in glioma cells.

Title: Decreased expression of caveolin-1 in FABP7-deficient astrocytes and its impact on the membrane lipid raft formation

Authors: *Y. KAGAWA, M. EBRAHIMI, K. SHARIFI, A. ISLAM, Y. YASUMOTO, H. MIYAZAKI, S. KAWAMURA, Y. YAMAMOTO, T. SAWADA, N. TOKUDA, Y. OWADA; Dept. of organ anatomy, Yamaguchi Univ. Grad. Sch. of Med., Yamaguchi, Japan

Abstract: [Introduction]Polyunsaturated fatty acids (PUFAs) have an important role as components of cell membrane, and control the cellular lipid metabolism to maintain the cell homeostasis. Fatty acid-binding
proteins 7 (FABP7), which has high affinity with omega-3 PUFAs, is strongly expressed by astrocytes and oligodendrocyte precursor cells in the brain. We previously showed that FABP7-deficiency in mice resulted in altered emotional behavior, and that FABP7 expression was altered in human schizophrenic brains. However, the precise role of FABP7 in astrocyte and how FABP7-deficiency is associated with schizophrenia pathology are still unknown. In this study, we examined the role of FABP7 in the astrocytes focusing on the lipid raft formation, which is essential for various receptor-mediated signal transduction in response to external stimuli. [Methods and Results]In the membrane lipid raft fractions separated by sucrose gradient centrifugation, the accumulation of lipid raft-associated proteins including TLR4, EGFR, and GFRα1 after the ligand stimulation was decreased in FABP7-KO astrocytes. The activation of MAPKs (ERK, p38, JNK) and NF-kB was also decreased in FABP7-KO astrocytes compared with WT as examined by western blot using anti-phosphorylated p-MAPKs and (p)-IkB antibodies. Interestingly, in qPCR analysis, the expression of caveolin-1, the main protein component of caveolae, was significantly decreased at transcriptional level in FABP7-KO astrocytes. Deletion analysis of Cav-1 gene by using luciferase reporter assay revealed that FABP7-dependent promoter was located in an approximately 200bp upstream from the start codon. [Discussion]It is suggested that FABP7 may control the lipid raft (caveolae) formation thorough regulating the expression of caveolin-1, thereby being involved in the response of astrocytes to various external stimuli.

Title: Inflammatory pain behaviour is attenuated in GPR84 knock-out mice

Authors: *L. C. NICOL[1], C. GENTRY[1], D. MCINNERNEY[1], J. B. DAVIS[2], M. MALCANGIO[1], S. B. MCMAHON[1];

Abstract: GPR84 is an orphan G-protein coupled receptor found in a range of immune cells. Under inflammatory conditions its expression is markedly induced in monocytes/macrophages and microglia and thus has been suggested to have a role in immunological and neuroinflammatory processes (Wang et al., 2006; Bouchard et al., 2007). Since accumulating evidence supports a critical role for neuronal-immune interactions in chronic pain generation, we studied the role of this receptor in inflammatory pain modulation.
GPR84 wild-type (WT) and knock-out (KO) C57BL/6 mice were generated and provided by GlaxoSmithKline. To examine the role of GPR84 in spinal microglia, mechanical, thermal or cold paw withdrawal thresholds of KO and WT mice were monitored over a 14 day period following either Complete Freund's Adjuvant (CFA) or lipopolysaccharide (LPS) administration. At the endpoint of the experiment, perfusion-fixed lumbar spinal cords were taken for immunohistochemical analysis of microglial markers Iba-1 and p-38 MAPK.
Following intraplantar CFA administration, GPR84 KO mice showed a 58% and 51% attenuation in the development of mechanical and cold hyperalgesia respectively, compared to WT littermate controls, which was significant. Interestingly, tactile mechanical thresholds dropped to a similar extent in both genotypes. In addition, CFA treatment caused significantly increased Iba1 and p-38 MAPK immunoreactivity in the ipsilateral dorsal horn of the spinal cord in both WT and KO compared to sham animals, with no difference between genotypes. Intrathecal LPS elicited significant mechanical allodynia 1 hr after injection in both genotypes. Iba1 and p-38 MAPK immunoreactivity in the lumbar spinal cord of WT or KO showed a similar bilateral increase compared to sham animals.
We conclude that GPR84 plays a role in the establishment of inflammatory pain. These data suggest that microglia do not contribute to the behavioural phenotype of GPR84 KO mice, as

following CFA or LPS there was no difference in microgliosis between genotypes. Furthermore, both genotypes exhibited a similar decrease in tactile mechanical paw withdrawal thresholds post intrathecal LPS, which is a CNS inflammatory model that selectively examines the microglia role. We therefore postulate that GPR84 expressed on peripheral macrophages may account for the observed attenuation of mechanical hyperalgesia of GPR84 KOs in both the CFA and LPS models.

Title: Fosb gene products regulate expression of C5ar1 and C5l2 genes and microglial activation

Authors: *H. NOMARU, K. SAKUMI, D. TSUCHIMOTO, Y. NAKABEPPU;
Div. Neurofunc. Genomics, MIB, Kyushu Univ., Fukuoka, Japan

Abstract: The Fosb gene encodes subunits of the activator protein-1 (AP-1) complex, and is involved in the regulation of gene expression in multiple signaling pathways. Among the Jun and Fos gene families, Fosb forms two types of mature mRNA by alternative splicing, Fosb and ΔFosb, that encode full length FOSB and truncated ΔFOSB proteins. ΔFOSB lacks the C-terminal transactivation domain of FOSB. FOSB and ΔFOSB act as transcriptional regulators yet little is known about their downstream target genes. We already reported Fosb-null mice exhibit depressive-like behaviors and increase anxiety-like responses. In addition, these mice displayed impaired neurogenesis in the adult hippocampus and spontaneous epilepsy. These results strongly suggest that Fosb gene products have important roles in prevention of neurological and psychiatric disorders. Extensive research of their function in the brain has primarily been focused

on neurons, while that in glial cells remains to be explored. In this study, we found that microglial cells express high levels of Fosb and ΔFosb mRNAs as seen in hippocampal neurons, and identified genes whose expression depends on Fosb gene products in microglia. Using microarray analysis, we found that expression levels of 6 genes are significantly altered, with a fold change ≥1.5 (ANOVA; $p<0.05$), between primary microglia isolated from wild-type and Fosb-null brains. Of the 6 genes, we further investigated C5ar1 and C5l2, both of which encode receptors for the complement anaphylatoxin, C5a, an inflammatory mediator of the innate immune system. In Fosb-null microglia, chemotactic responsiviness tward C5a as well as levels of C5ar1 and C5l2 mRNAs were significantly decreased compared with wild type. We further investigated effect of disruption of Fosb gene on kainic acid (KA)-induced excitotoxicity in the hippocampus. We found Fosb-null mice exhibited an increased resistance to KA-induced seizure. Twenty four hours after KA administration, expression of both C5ar1 mRNA and C5ar1 protein was significantly increased in wild-type but not Fosb-null hippocampus. While level of C5l2 mRNA was not increased after KA administration, the basal level of C5l2 mRNA in Fosb-null hippocampus was significantly lower than that in wild type. Furthermore, levels of mRNAs for IL-6 and TNF-α in wild-type but not Fosb-null hippocampus were significantly increased accompanied by microglial activation, especially in CA3 region after KA administration. We thus concluded that Fosb gene products are indispensable to induce neuroinflammation through regulating expression of C5ar1 and C5l2 genes in microglia.

Title: Role of aryl hydrocarbon receptor in LPS-induced microglial activation

Authors: *F.-S. SHIE[1], C.-H. LIN[2], P.-C. HSU[3], Y.-P. YEH[3], Y.-Y. SUN[4], C.-Y. KUAN[4], J.-H. ZHUO[5], Y.-H. LEE[3];

Univ., Taipei, Taiwan

Abstract: Microglia become activated triggering various immune responses during the pathogenesis in many neurodegenerative diseases. Microglial activation is a double-edged sword and the resulting consequences of microglial activation can be beneficial or detrimental. However, the underlying mechanisms are not understood fully. Here, we reported that lipopolysaccharide (LPS) promoted activation of aryl hydrocarbon receptor (AhR), a ligand-activated transcription factor, and increased expression of AhR in primary microglia. LPS-induced expression of AhR can be diminished by pretreatment of ERK1/2 inhibitor, U0126, suggesting that ERK1/2 signaling may be involved. Importantly, small interfering RNA against AhR significantly attenuated LPS-induced microglial immune responses as evidenced by reduced expressions of inducible nitric oxide synthases (iNOS) and cyclooxygenase-2 (COX-2) and by suppressed secretion of pro-inflammatory cytokines, including tumor necrosis factor (TNFα) and interleukin-6 (IL-6). Formylindolo[3,2-*b*]carbazole (FICZ), an endogenous AhR ligand, also activated AhR in primary microglia. However, the LPS-induced microglial immune responses were alleviated by the co-treatment of FICZ. Taken together, our results suggest that AhR may function to aggravate LPS-induced microglial activation, while activation of AhR may counteract the deteriorating effects in a ligand-dependent manner. Therefore, further understanding the multi-functional aspects of microglial AhR can depict the regulatory machinery of microglial activation and will confer molecular basis for developing the treatment of the diseases.

Title: Dopamine attenuates LPS-induced cytokine expression in mouse microglial BV-2 cells

Authors: *Y. SUGINO, Y. YOSHIOKA, Y. WADA, A. YAMAMURO, Y. ISHIMARU, S. MAEDA;
Setsunan Univ., Hirakata, Japan

Abstract:
The proinflammatory cytokines produced by activated microglia have been proposed to play a pathogenetic role in Parkinson's disease. The most important neuropathological alteration in Parkinson's disease is the loss of dopaminergic neurons in the substantia nigra, followed by a severe depletion of dopamine in the striatum. From these observations, we hypothesize that dopamine may negatively regulate cytokine production by activated microglia. To reveal this hypothesis, in this study, we investigated the effect of dopamine on LPS-induced mRNA expression of cytokines in mouse microglial cell line BV-2. The mRNA levels of IL-1β, IL-6 and TNF-α were determined by real-time RT-PCR, and the protein levels of NF-κB p65 and IκBα were determined by Western blotting. In BV-2 cells, LPS increased mRNA levels of IL-1β, IL-6 and TNF-α in a concentration-dependent manner. Pretreatment with dopamine (1-30 μM) for 24 h concentration dependently attenuated the LPS-induced mRNA expression of these cytokines. Neither SCH23390 nor sulpiride, D_1-like and D_2-like dopamine receptor antagonists, respectively, affected the attenuation of LPS-induced mRNA expression of cytokines by dopamine. In addition, pretreatment with CY208-203 or bromocriptine, D_1-like and D_2-like dopamine receptor agonist, respectively, did not affect LPS-induced mRNA expression of cytokines. N-Acetylcysteine (NAC), a free radical scavenger, inhibited the attenuation of LPS-induced mRNA expression of cytokines by dopamine. On the other hand, hypoxanthine/xanthine oxidase, a super oxide generating system, did not affect LPS-induced mRNA expression of cytokines. Dopamine concentration-dependently increased the level of quinoproteins, and the increase was inhibited by NAC. LPS increased the nuclear levels of NF-κB p65, and decreased the levels of IκBα in cytosol. The increase in the nuclear levels of NF-κB p65 was attenuated by dopamine. On the other hand, dopamine did not affect the LPS-induced decrease of IκBα. NAC inhibited the attenuation of LPS-induce increase in the nuclear levels of NF-κB p65 by dopamine. These results suggest that dopamine attenuates LPS-induced expression of cytokines by inhibiting the nuclear translocation of NF-κB p65 through the formation of quinoprotein in BV-2 cells. These findings indicate that the decrease of dopamine may enhance cytokine production by activated microglia and result in progression of Parkinson’s disease.

Title: Up-regulation of secretory phospholipases A2-group V in microglial cells: role of ERK1/2 in IFN-γ and LPS induced inflammatory signaling pathways

Authors: *Y. ZONG, J. JIANG, D. Y. CHUANG, A. SIMONYI, G. Y. SUN;
Biochem., Univ. of Missouri, Columbia, MO

Abstract: Secretory phospholipases A2 (sPLA2s) belong to a superfamily of enzymes responsible for hydrolysis of acyl ester at the *sn-2* position of glycerophospholipds. Among the more than 12 isoforms of sPLA2s in mammals, many studies have focused on group IIA because of its potential role in inflammatory responses and its ability to induce neuronal death via apoptosis. While sPLA2-IIA is expressed in rat astrocytes, our earlier studies failed to find it in rat or murine immortalized microglial cells. However, sPLA2-V is found constitutively present in rat and murine microglial cells, and is up-regulated upon treatment with pro-inflammatory cytokines (mixture of TNF-α, IL-1β and IFN-γ) as well as endotoxin (lipopolysaccharides, LPS). Our goal of this study is to elucidate the mechanism for regulation of sPLA2-V expression in microglial cells. Unlike sPLA2-IIA, which is normally up-regulated through the NF-κB pathway without the requirement of IFN-γ, up-regulation of sPLA2-V expression in microglial cells can be induced by exposing cells to IFN-γ alone; and IFN-γ can enhance sPLA2-V up-regulation by cytokines and LPS. Further studies led to results showing that besides the JAK-STAT1 pathway, IFN-γ can activate several other signaling pathways in microglial cells. For example, IFN-γ can activate the MAPK pathway leading to ERK1/2 phosphorylation, and in turn, p-ERK is important for production of reactive oxygen species (ROS) through phosphorylation of cytosolic subunits of NADPH oxidase. In addition, IFN-γ-induced ERK1/2 phosphorylation could enhance the NF-κB pathway through phosphorylation of IKK. Taken together, our data together with other studies demonstrate the pro-inflammatory role of sPLA2-V in microglial cells and its up-regulation through a signaling pathway involving IFN-γ, ERK1/2, IKK and ROS production. Understanding this oxidative pathway is important for development of therapeutic targets to suppress microglial inflammatory responses and interaction with neuronal behavior.

Title: Role of cytosolic phospholipase A2 in lipopolysaccharide- and interferon gamma-induced inflammatory responses in microglial cells

Authors: *D. Y. CHUANG[1], Y. ZONG[1], J. JIANG[2], A. SIMONYI[1,2], Z. GU[1,3], G. Y. SUN[1,2,3]; [1]Interdisciplinary Neurosci. Program, [2]Dept. of Biochem., [3]Dept. of Pathology and Anatom. Sciences, Ctr. for Translational Neurosci., Univ. of Missouri, Columbia, MO

Abstract: Oxidative stress and inflammatory responses have been shown to contribute to the pathophysiology of numerous neurological diseases, including Alzheimer's disease, Parkinson's disease, acute stroke, and infections of the brain. There is increasing evidence for the role of microglial cells in mediating the oxidative and inflammatory responses and propagating damage to other cell types in the brain. Microglial cells readily respond to endotoxin (lipopolysaccharide, LPS) and cytokines and upon activation, they further generate additional pro-inflammatory cytokines, as well as reactive oxygen species (ROS) and nitric oxide (NO). In our recent studies, we have demonstrated the important role of extracellular signal-regulated kinase (ERK1/2) and reactive oxygen species (ROS) in transducing inflammatory signals that leads to iNOS expression in microglia after stimulation with LPS or interferon-gamma (IFNg). Microglia also express relatively high levels of cytosolic phospholipase A2 (cPLA2), an enzyme known for regulation of membrane phospholipid homeostasis and release of arachidonic acid (AA) for synthesis of eicosanoids. Activity of cPLA2 is highly determined by the phosphorylation state of the Ser505 residue, largely through the mitogen-activated protein kinases (MAPKs), namely ERK1/2 and p38. However, whether cPLA2 downstream plays a role in modulating microglial oxidative and inflammatory responses has not been investigated in detail. In this study, we observed evidence for a link between cPLA2 and signaling pathways for LPS/IFNg-induced NO and ROS production in microglial cells. With the immortalized mouse microglia BV-2 cell line, inducible nitric oxide (iNOS) expression and its subsequent NO production due to treatment with LPS or IFNg were both dose-dependently inhibited by AACOCF3, an inhibitor of cPLA2 and iPLA2. AACOCF3 exerted a much greater inhibitory effect on LPS stimulated NO as compared

to IFNg stimulated NO. A similar trend for effect of AACOCF3 is observed in ROS production, which has been shown in previous study to generate from the active NADPH oxidase complex downstream of ERK1/2 activation (Chuang et al., J Neuroinflammation, 2013). Interestingly, inhibition of pERK1/2 with U0126, a MEK1/2 inhibitor, shows reciprocal effect, i.e. U0126 was more potent in inhibiting IFNg-stimulated NO/ROS than LPS-stimulated NO/ROS. Taken together, results show that while cPLA2 is shown to play a role in modulating inflammatory responses in microglia cells, its regulation may be mediated by different receptor activation pathways. These cross-talk mechanisms will be the center of investigation in future studies.

Title: Adenosine A2A receptors control the metabolic changes associated with microglia activation as revealed by NMR isotopomeric analysis

Authors: *C. LEMOS[1], G. CRISTÓVÃO[2], I. JARAK[2], R. A. CUNHA[2], C. GOMES[2], R. A. CARVALHO[2];
[2]Ctr. for Neurosciences and Cell. Biol., [1]Coimbra Univ., Coimbra, Portugal

Abstract: Microglia cells play a critical role in brain homeostasis. Both physiological changes (e.g. synaptic activity) or disease-associated abnormalities (e.g. bacterial or proteinaceous antigens) trigger a metabolic adaptation of microglia to sustain adequate reactivity, namely proliferation. The modulation of microglia proliferation is of potential therapeutic interest to manage brain disorders, as heralded by the ability of adenosine A2A receptor (A2AR) antagonists to control microglia proliferation (Gomes et al., 2013, J Neuroinflamm 10:16) and alleviate brain diseases (Gomes et al., 2011, Biochem Bipohys Acta 1808:1380). We now tested if A2AR control the mandatory metabolic adaptation that enables microglia to respond to "danger" signals.
We used 1H- and 13C- NMR spectroscopy to characterize some key metabolic features

(glycolytic activity, assessed by lactate/alanine ratio, and coupling between glycolytic and Krebs cycle fluxes, gauged as the 13C incorporation rate into glutamate) of non-activated and activated (with lipopolysaccharide, LPS, 100 ng/mL) N9 microglia cells, in the absence or presence of the selective A2AR antagonist, SCH 58261 (50 nM, for 48h).
Non-activated cells exhibited a low lactate/alanine ratio and high 13C incorporation rate into glutamate. LPS increased the lactate/alanine ratio (associated with increased glycolysis and reduction of alanine content) and abolished the 13C incorporation into glutamate. A2AR blockade did not affect the metabolic profile of non-activated cells, but modulated LPS-induced changes in a time-dependent manner: the initial counteraction of glycolytic fluxes (2-6h) was followed by a return to basal levels by the end of the incubation period (48h); this time-dependent modulation was also noticeable by an increase of the incorporation of 13C in glutamate in the steady state isotopomer analysis performed in cell extracts.
These findings indicate that LPS determines a metabolic reshaping of microglia cells to cope with LPS-induced proliferation. A2AR blockade, which prevents LPS-induced proliferation (Gomes et al., 2013), also impacts on the metabolic adaptation of activated microglia, optimizing the coupling between glycolysis and Krebs cycle fluxes.

Title: Prostaglandin E2 exerts anti-inflammatory effects by inhibiting microglial production of superoxide through a novel pathway

Authors: *S.-H. CHEN[1], E. OYARZABAL[2], J.-S. HONG[1];
[1]Natl. Inst. of Envrn. Hlth. Sci., Research Triangle Park, NC; [2]Natl. Inst. of Envrn. Hlth. Sci., RTP, NC

Abstract: Prostaglandin E2 (PGE2) is a well-known pro-inflammatory mediator, but recent studies indicate that PGE2 also has anti-inflammatory functions. PGE2 exerts its actions by binding to one or several of its receptors (EP1 to EP4) coupled to different G proteins and linked to different second messengers. The anti-inflammatory effects of PGE2 are mediated by EP2 and EP4 receptors, which trigger cAMP production, leading to protein kinase A (PKA) activation.

However, several studies suggest that PKA may not be the only pathway mediating the anti-inflammatory effect of PGE2. The main purpose of this study was to search for the novel PKA-independent pathways of PGE2. Unlike previous studies that used pharmacological concentrations of PGE2 (100 nM to 10 microM), we used physiological concentrations of PGE2 (<10 nM) for studying its anti-inflammatory effect in LPS-treated rodent mixed glia cultures. Our results show that PGE2 inhibited superoxide production in microglia with an IC50 of 0.1 nM which is 10 to 100-fold lower than the binding affinity of EP2 and EP4 receptors. Meanwhile, agonists for all the EP receptors mimicked this inhibition with similar affinities. PGE2-elicited inhibition of superoxide production was not affect in EP2-deficient microglia,indicating the existence of an EP2 receptor-independent mechanism. Pharmacophore analysis of the structure of these EP receptor agonists revealed a common binding site shared by these agonists which maybe associated with superoxide production. Further mechanistic studies revealed that PGE2-elicited reduction of LPS-induced superoxide production was mediated through the inhibition of the key microglial superoxide-producing enzyme, phagocyte NADPH oxidase (PHOX), via binding to the catalytic subunit of PHOX gp91^{phox}. Furthermore, this novel superoxide inhibitory effect is associated with PGE2-induced reduction in TNFa production in LPS-treated microglia. The evidence came from studies showing that 1) inhibition of TNFa production can be achieved in a concentration of PGE2 (10 nM) that did not increase microglial cAMP levels, 2) inhibitors of adenylate cyclase or PKA failed to reverse PGE2-elicited suppression of TNFa, and 3) PGE2-elicited inhibition of TNFa was not observed in microglia deficient in PHOX. Taken together, or study revealed a PHOX dependent and cAMP/PKA-independent novel pathway mediating the anti-inflammatory effects of physiological concentrations of PGE2.

Title: Inhibition of phosphoinositide-dependent P2X4 receptor channel by Gq-coupled P2Y6 receptor in microglia

Authors: *L.-P. BERNIER[1,2], A. ASE[2], E. BOUE-GRABOT[3], P. SEGUELA[2];
[1]Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada; [2]Montreal Neurolog. Inst., McGill Univ., Montreal, QC, Canada; [3]Inst. des maladies neurodégénératives, Univ. Bordeaux Segalen, Bordeaux, France

Abstract: ATP-gated P2X4 receptor channels expressed in spinal microglia actively participate in central sensitization, making their functional regulation a key process in chronic pain pathologies. P2Y6 metabotropic Gq-coupled receptors, also expressed in microglia, are involved in the initial response to nerve injury, triggering phagocytosis upon activation by UDP. It has been reported recently that expression of both P2X4 and P2Y6 is upregulated in activated microglia following nerve injury. We show here, in resting as well as LPS-activated primary microglia, that P2Y6 decreases P2X4-mediated calcium entry and inhibits the dilation of P2X4 channels into a large-conductance pore measured with a YO-PRO-1 uptake assay. Furthermore, P2Y6 activation modulates the ATP-dependent migration of microglia, a process likely involved in their shift from migratory to phagocytic phenotype. Reconstituting the P2X4-P2Y6 interaction in recombinant systems shows that P2Y6 activation decreases P2X4 current amplitude, activation and desensitization rates, and reduces P2X4 channel permeability to the large cation NMDG+. Phospholipase C-mediated hydrolysis of the phosphoinositide PI(4,5)P2, a necessary cofactor for P2X4 channel function, underlies this inhibitory crosstalk. As extracellular levels of both ATP and UDP are increased in the spinal cord following nerve injury, the control of P2X4 activity by P2Y6 might play a critical role in regulating neuropathic pain-inducing microglial responses.

Title: Involvement of microglial P2X7 receptors in morphine analgesic tolerance is mediated by mu-opioid receptor signalling

Authors: H. L. LEDUC-PESSAH[1,2,3], C. FAN[1,2,3], *T. TRANG[1,2,3];
[1]Comparative Biol. & Exptl. Med., [2]Physiol. & Pharmacol., [3]Hotchkiss Brain Inst., Univ. of Calgary, Calgary, AB, Canada

Abstract: Morphine is indispensable in the treatment of acute and chronic pain. However, its use is limited by the development of analgesic tolerance, such that higher and more frequent doses are necessary for achieving the same level of pain control. In rats, we found that the development of morphine tolerance correlated with an increase in spinal expression of ATP-gated P2X7 receptors (P2X7R). This increase was restricted to microglia residing in the spinal dorsal horn, and pharmacologically blocking P2X7Rs with the selective P2X7R antagonist, A740003, attenuated the development of tolerance but did not reverse established tolerance. Likewise, in microglial BV2 cells morphine treatment caused a dose dependent upregulation of P2X7Rs that was suppressed by the mu-receptor antagonist, CTAP. By contrast, activating mu receptors with DAMGO markedly upregulated total P2X7R protein expression in the microglia. Although P2X7R mRNA levels were not affected by morphine treatment, we detected an increase in cell surface expression of P2X7Rs that was concomitant with enhanced BzATP-evoked influx of extracellular Ca2+. Taken together, our findings suggest that mu-opioid receptor signaling critically regulates expression of microglial P2X7Rs involved in the development of morphine analgesic tolerance.

Title: Activation of poly(ADP-ribose) polymerase-1 in males and females: Comparisons using PAR immunostaining and a PARP activity assay

Authors: *Y. CHEN[1,2], S. WON[1], C. HEFNER[1], Y. SHEN[1], Y. XU[2], R. SWANSON[1];
[1]Neurol., Dept. of Neurology, Univ. of California, San Francisco, San Francisco, CA; [2]Dept. of Neurology, Affiliated Drum Tower Hosp. of Nanjing Univ. Med. School, 321 Zhongshan Road, Nanjing, Jiangsu, 210008, P. R. China, Nanjing, China

Abstract: Poly(ADP-ribose)polymerase-1 (PARP-1) is an abundant nuclear enzyme that consumes cytosolic NAD^+ to form poly(ADP-ribose) polymers (abbreviated as PAR) on histones and other proteins in the vicinity of single strand DNA breaks. These breaks occur normally in the course of gene transcription, and occur pathologically in response to oxidative stress, excitotoxicity, and ischemia reperfusion. PAR formation provides a scaffolding for protein complexes involved in single strand DNA repair, but extensive PAR formation can deplete cytosolic NAD^+ concentrations and precipitate cell death. PARP-1 activation also has signaling and regulatory effects in cells, and in particular it facilitates NF-kB -driven gene transcription during inflammatory responses. The effect of PARP inhibitors on PARP-1 - induced cell death and inflammatory responses are strikingly different in males and females, for reasons that remain obscure. A key question is whether these gender-specific effects of PARP inhibitors occur downstream of PARP activation, or whether instead PARP activation is inherently different in male and females under comparable stimuli. For technical reasons this has been difficult to resolve. One way to evaluate PARP-1 activity in brain sections is by Western blots or immunostaining for the PARP-1 product, PAR. However, the amount of PAR present at any given time may be an unreliable indicator of enzyme activity, because PAR levels are also affected by the rate of PAR degradation. For this reason we adapted a PARP activity assay to address this issue. The method employs biotin-labeled NAD^+, which is then trapped in both PAR and PAR degradation products, and permits histochemical evaluation of PARP activity in both cultured cells and ex vivo brain sections. Our studies show the feasibility of comparing these two techniques in both cell culture and ex vivo brain sections, which indicate that the effects PARP inhibitors on the NF-kB activity may be different at short and long term at points following inflammatory stimuli.

Title: Activation of neuronal NMDA receptors triggers rapid microglial process outgrowth

Authors: *L. DISSING-OLESEN, J. LEDUE, R. RUNGTA, H. CHOI, B. MACVICAR; Brain Res. Centre, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Microglia exhibit motile processes that survey surrounding synapses by contacting dendritic spines in response to unknown signals. Microglia extend processes in response to ATP and activation of neuronal NMDA receptors (NMDAR) has been demonstrated to trigger opening of the ATP releasing channel; pannexin 1 (Panx1). Therefore we tested the hypothesis that activation of neuronal NMDAR triggers ATP efflux through opening of Panx1 channels to signal to microglia. Here we show that activation of neuronal NMDAR indeed triggers ATP-mediated microglial process outgrowth but surprisingly the release of ATP occurred independently of Panx1 opening.

We used two-photon scanning microscopy of EGFP+ve microglia in acute hippocampal brain slices to confirmed that extracellular ATP triggered a characteristic microglial process outgrowth that reversed when ATP was removed or when purinergic receptors were blocked. Brief NMDAR activation in the CA1 stratum radiatum triggered a similar microglial process outgrowth. This microglia outgrowth in response to NMDA was reversible and repeatable, demonstrating that the microglial response was not due to permanent excitotoxic damage. We also observed that the process outgrowth was more pronounced and occurred more reliably following multiple NMDA applications. The underlying mechanism(s) for this 'priming effect' is under investigation.

The microglial response was selective to NMDAR stimulation as it was blocked by APV, the selective NMDAR antagonist, but still occurred in the presence of CNQX and TTX to block AMPA receptors and Na+ channels, respectively. The microglia were responding to the release of ATP triggered by NMDA application not NMDA itself because microglia process outgrowth was abolished by purinergic receptor blockade. Surprisingly, the commonly used blocker of pannexin and connexin channels, carbenoxolone did not block NMDA-induced microglia process outgrowth although as a control we showed carbenoxolone did block dye flux through connexin gap junctions. To further validate this result, we established a modified fixation protocol that allowed us to fix the whole brain slice and preserve the microglia morphology at the time of fixation. Immunohistochemical labeling of microglia in tissue from Panx1-deficient mice subjected to multiple NMDA applications confirmed that outgrowth occurred independent of Panx1. Thus the mechanism(s) of NMDA-mediated ATP release is currently under investigation.

Title: Characterization of cortical and sub-cortical glia following toll-like receptor stimulation

Authors: *C. WINLAND[1], S. G. DANIELE[2], A. G. EDWARDS[2], K. MAGUIRE-ZEISS[2]; [1]Georgetown Univ., Fairfax, VA; [2]Georgetown Univ., Washington, DC

Abstract: Neuroinflammation coincides with the progression of neurodegenerative diseases such as Alzheimer's, Parkinson's, and ALS. It is well established that activated microglia and astrocytes release neurotoxic molecules including interleukin-1 beta (IL-1β), tumor necrosis factor (TNFα), and nitric oxide (NO). The release of these pro-inflammatory molecules may exacerbate neuronal cell loss through enhanced oxidative stress and/or cytokine-mediated cell death. However, the difference between regionally distinct microglia and astrocyte responses to brain-relevant stimuli are not well characterized. Therefore, the present study compared release of pro-inflammatory molecules from microglia and astrocytes stimulated with toll-like receptor ligands and the Parkinson's disease proteinα-synuclein. Primary microglia and astrocytes were cultured from cortical or subcortical areas of C57/Bl6 mice. Following stimulation cells, lysates, and media were harvested and analyzed for proinflammatory molecules. There were no cell type or regional differences in glial responses to TNFαproduction following stimulation with a TLR2 or TLR4 ligand. However, immunocytochemistry for Iba1 revealed subtle morphological differences between cortical and subcortical microglia. Interestingly, oligomeric α-synuclein elicited greater TNFαrelease from subcortical microglia when compared to microglia cultured from cortical areas. These results demonstrate differential regional activation of microglia to a Parkinson's disease relevant protein, which supports the need for more studies to elucidate whether this region specific activation plays a role in Parkinson's disease pathogenesis.

Title: Involvement of MAP kinase cascade in M-CSF-triggered microglial proliferation in transected rat facial nucleus

Authors: *S. YAMAMOTO[1], S. KOHSAKA[2], K. NAKAJIMA[1,2];
[1]Dept. of Bioinformatics, Fac. of Engineering, Soka Univ., Tokyo, Japan; [2]Dept. of Neurochemistry, Natl. Inst. of Neurosci., Tokyo, Japan

Abstract: Transection of rat facial nerve leads to an increase of microglial cell number in the ipsilateral facial nucleus. In the previous study, we demonstrated that up-regulated macrophage-colony stimulating factor (M-CSF) in the transected facial nucleus triggers the induction of cFms (receptor for M-CSF), proliferating cell nuclear antigen (PCNA) and cell cycle-associated proteins, including cyclins, cyclin-dependent protein kinases (Cdks) and Cdk inhibitors (CdkIs) in microglia and causes the microglia to divide. However, the signaling mechanism of M-CSF-triggered microglial proliferation remains to be elucidated. In the present study, we analyzed the signaling cascade downstream of cFms. Experiments in vitro using a cFms inhibitor indicated that M-CSF-cFms signaling leads to upregulation of the levels of cFms, PCNA, cyclin A and cyclin D in microglia. The role of cyclin A/Cdk2 activity in M-CSF-dependent microglial proliferation was ascertained by using the specific inhibitor purvalanol A. C-Jun N-terminal kinase (JNK) was suggested to be associated with M-CSF-dependent induction of cyclins and PCNA, while p38 was associated with cFms induction. Both JNK and p38 were proved to be phosphorylated by stimulation with M-CSF, and were significantly suppressed by pretreatment with cFms inhibitor. Furthermore, we demonstrated that mitogen activated protein kinase activated protein kinase-2 (MAPKAPK-2), cyclic AMP responsive element binding protein (CREB) and mitogen-and stress-activated protein kinase-1 (MSK1) are activated in M-CSF stimulated microglia. These signaling molecules are thought to be located at downstream of JNK/p38 because their phosphorylations were suppressed in the presence of JNK/p38 inhibitors. Our results indicated that MAPKAPK-2, CREB and MSK1 are involved in JNK/p38 cascade downstream of cFms in M-CSF-stimulated microglia.

Title: Osteopontin expression by dying neurons in oxygen-glucose-deprived hippocampal slice cultures

Authors: T.-R. RIEW[1], Y.-J. SHIN[1], J.-H. PARK[1], H. KIM[2], *M.-Y. LEE[1];
[1]Dept Anat, [2]Integrative Res. Support Center, Lab. of Electron Microscope, Catholic Univ. Med. Col., Seoul 137-701, Korea, Republic of

Abstract: Osteopontin (OPN), an adhesive glycoprotein, has recently been proposed to act as an opsonin that facilitated phagocytosis of neuronal debris by macrophages in the ischemic brain. Here, the present study was aimed to gain further insight into the relationship between OPN induction and neuronal cell death using organotypic hippocampal slice cultures subjected to ischemia-like oxygen-glucose deprivation (OGD). Double or triple-labeing study using markers of cell death such as propidium iodide uptake or the Tdt-dUTP terminal nick-end labeling (TUNEL) revealed revealed that OPN expression is induced exclusively in dying neurons and not in viable neurons after OGD. Immunoperoxidase electron microscopy revealed that labeled neurons whose cell bodies shrank and possessed condensed nuclei with small patches of chromatin clumping and many swollen organelles and vacuoles in the perikaryal region, displayed a mixture of necrotic- and apoptotic-like features after OGD. OPN Immunoreaction products in labeled neurons were diffusely localized throughout the nucleus and cytoplasm, and were also associated with the rough endoplasmic reticulum and mitochondria, while the reaction products in microglia were strictly localized to the Golgi apparatus, and not associated with other organelles or with the nucleus. In addition, phagocytic microglial cells were frequently located in a close vicinity of the labeled dying neurons, and contained labeled cell debris inside their cytoplasm, indicating that the labeled neurons fragmented into cell debris that was engulfed by microglia synthesizing and secreting OPN. Thus, our data suggest that OPN induction may be involved in the neuronal cell death and ongoing microglial phagocytosis of dead neurons during OGD and reperfusion in hippocampal slice cultures.

Title: Genetic depletion of tau prevents cognitive impairment in type 1 diabetes-like mouse model

Authors: *D. BAGLIETTO-VARGAS[1], S. ABBONDANTE[1], C. J. RODRIGUEZ-ORTIZ[1,2], T. ESTRADA-HERNANDEZ[1], R. MEDEIROS[1], F. M. LAFERLA[1];

Abstract: Growing evidence indicates a significant association between diabetes and Alzheimer disease (AD). Patients affected by diabetes show an increased risk of developing AD. However, the underlying molecular mechanisms connecting these two disorders are still not well understood. Here, we investigate the microtubule-associated protein tau (MAPT) as a new perspective on the association between AD and diabetes. To determine whether diabetes causes cognitive decline by tau dependent mechanism, we treated non-transgenic (Ntg) and tau knockout (tauKO) mice with streptozotocin (STZ), causing type 1 diabetes-like disease (T1D). Our study shows that tau is a fundamental mediator for T1D-like disease to induce cognitive impairment, and its dysregulation causes reduction in synaptic proteins levels and cognitive decline. Concomitantly, we demonstrate the novel finding that depletion of endogenous tau mitigates behavioral impairment and synaptic deficits induced in T1D-like mice. Therefore, our data reveal that tau is a key molecular factor necessary for T1D-like disease to induce cognitive decline, and represents a potential therapeutic target for diabetes and AD patients.

Title: Effects of differential exercise training on hippocampal function using a triple-transgenic mouse model of alzheimer's disease

Authors: *T. D. TRAN[1], Q. LU[2], S. BAREISS[3];
[1]Dept Psychology, [2]Anat. and Cell Biol., East Carolina Univ., GREENVILLE, NC; [3]Physical Therapy, East Carolina Univ., Greenville, NC

Abstract: Alzheimer's disease (AD) is the primary cause of dementia and is characterized by severe brain, behavior, and cognitive dysfunctions that hinder everyday living for those affected. AD is the 6th leading cause of death in the United States and comprises 50-80% of dementia cases worldwide. In the past several years, a mouse model bearing three gene mutations of PS1-M146V (presenilin), APP-Swe (amyloid precursor), and tauP301L (tau) proteins (i.e., 3xTg model) has received considerable attention in elucidating pathology and neurocognitive deficits observed in AD. This mouse model has shown that significant cognitive decline and AD pathology usually occurs at 6 months of age. Research supports the notion that exercise maintains and improves cognitive function in aging, and remains the best non-pharmaceutical approach to combat cognitive decline and the progression of AD in humans (Blacker et al., 2007; Booth et al., 2002). Indeed, human and animal studies have shown that exercise may protect against cognitive decline and pathology (e.g., Cho et al., 2003; Dustman et al., 1984; Um et al., 2008). In this study, we examined whether chronic, differential exercise therapy affects hippocampal-based cognitive function using the spatial version of the Morris water maze. Our hypothesis is that increasing doses of exercise in 3xTg mice would attenuate the behavioral and pathological hallmarks of AD. There were six exercise groups: (1) sedentary controls (S-WT, S-3xTg); (2) mice that received exercise training once per week (1x-WT, 1x-3xTg); and (3) mice that received exercise training three times per week (3x-WT, 3x-3xTg). Prior to reaching 6 months of age, all exercise groups received 90 days of training and in each session they ran at a rate of 8.0 m/min for 60 min with a 5-min warm up and cool down. Two days afterwards, they received water maze testing that consisted of 4 days of acquisition (4 trials/day) and 1 day of memory retention with a single probe trial. The following day, brain tissue was harvested for examination of changes in biochemical and immunohistological markers of AD. Results showed that in general, mice that exercised had better recall performance, particularly when compared to sedentary 3xTg mice. Comparison of 3xTg groups showed that both exercise groups benefited from their respective training regimens in relation to the sedentary 3xTg group. Title: Dissecting the role of mTOR in Alzheimer's disease

Authors: *A. CACCAMO[1], M. F. LÓPEZ-ARANDA[2], A. J. SILVA[2], S. ODDO[1];
[1]Univ. of Texas Hlth. Sci. Ctr. SA, San Antonio, TX; [2]UCLA, Los Angeles, CA

Abstract: Accumulation of Aβ and tau is a critical event in Alzheimer's disease (AD); however, the molecular mechanisms leading to Aβ and tau accumulation remain unclear. Age is a major risk factor for AD, suggesting that molecular changes contributing to the aging process may facilitate Aβ and
tau accumulation. Here, we use multiple animal models and complementary genetic and pharmacological approaches to show that dysregulation of the mammalian target of rapamycin (mTOR) contribute to Aβ and tau accumulation. Specifically, we first show that there is an interrelation between Aβ and mTOR. Indeed, Aβ causes mTOR hyperactivity, which in turn further facilitates Aβ accumulation. Hyperactive mTOR also facilitate tau expression and phosphorylation. Toward this end, we also show that show that genetically increasing mTOR activity elevates
endogenous mouse tau levels and phosphorylation. Complementary to it, we further demonstrate that pharmacologically reducing mTOR signaling with rapamycin ameliorates tau pathology and the associated behavioral deficits in a mouse model overexpressing mutant human tau. In summary, we show that mTOR, a key kinase involved in controlling protein homeostasis, represent a link between Aβ and tau accumulation. Given the overwhelming evidence showing that reducing mTOR signaling increases lifespan and health span, the data presented here have profound clinical implications for aging and AD and provide the molecular basis for how aging may contribute to this insidious disorder. Additionally, these results provide pre-clinical data indicating that reducing mTOR signaling may be a valid therapeutic approach for AD.

Title: Mitochondrial O-GlcNAc modification in the brains of 5XFAD mice

Authors: *H. CHOI, C. KIM, M.-Y. CHA, I. MOOK-JUNG;
Col. of Med., Seoul Natl. Univ., Chongro-Gu, Seoul, Korea, Republic of

Abstract: Mitochondria are the essential organelles to supply cellular energy and maintain Ca^{2+} homeostasis. Dysfunctional mitochondria also have relevance in several human diseases, including Alzheimer's disease (AD). Mitochondrial dysfunctions occur in the early stages of AD. These changes are induced by amyloid beta (Aβ), one of the major hallmarks of AD. It is also well known that glucose metabolism is disrupted in the brains of AD patients. *O*-GlcNAcylation (O-GlcNAc) is similar to phosphorylation, which is a post-translational modification that occurs at the same sites as phosphorylation (Ser or Thr residues) and regulates diverse cellular processes. Since *O*-GlcNAc of proteins is regulated by intracellular glucose metabolism and AD patients show the reduced glucose metabolism in the brain, it is reasonable to predict the decrease of *O*-GlcNAc proteins in AD brains. However, it has not yet known the difference of O-GlcNAcylated proteins between normal subject brains and AD patient's brains. In the present study, we focused on Mitochondrial O-GlcNAcylated proteins in the brains of 5XFAD mice, which is AD animal model. Mitochondrial proteins were analyzed by using LC-MS/MS methods. We identified and quantified novel O-GlcNAcylated mitochondrial proteins in the brains of 5XFAD mice.

Title: Mesenchymal stem cells enhance autophagy and increase beta-amyloid clearance in Alzheimer's disease models

Authors: *J. SHIN, H. PARK, H. KIM, S. OH, P. LEE;
Dept. of Neurol., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract:
Alzheimer's disease (AD) is characterized by neuronal loss and accumulation of abnormal amyloid β (Aβ) and tau proteins. Autophagy is a major degradation pathway for abnormal aggregated proteins and organelles that cause various neurodegenerative diseases. Current evidence suggests a central role for autophagy in AD pathogenesis, and dysfunction in the autophagic system may lead to Aβ accumulation.
Mesenchymal stem cells (MSCs) secrete various cytotropic factors that have neuroprotective effects through complex mechanisms such as modulation of neuroinflammation, enhancement of cell survival signals,and modulation of ubiquitinated proteins. In the present study, we investigated whether MSCs could enhance autophagy and thus exert a neuroprotective effect through modulation of Aβ clearance using in vitro and in vivo AD models. In Aβ-treated neuronal cells co-cultured with MSCs, MSCs increased cellular viability and enhanced LC-II expression compared with cells treated with Aβ only. Immunofluorescence analysis revealed that MSC treatment in Aβ-treated neuronal cells increased the LC3-positive autophagosomes that were co-localized with a lysosom. Additionally, cathepsin B mRNA expression, the major protease in lysosomes, was significantly increased in neuronal cells co-cultured with MSCs; treatment with chloroquine, a lysosomal inhibitor, significantly attenuated the increase in cell survival in cells co-cultured with MSCs. Ultrastructural analysis evealed that most autophagic vacuoles in Aβ-treated cells were not fused with lysosomes, whereas a large portion of autophagosomes were on joined with lysosomes in MSC-treated cells. Furthermore, MSC treatment markedly increased Aβ immunoreactivity co-localized within lysosomes and decreased intracellular Aβ levels compared with Aβ-treated cells. In an Aβ-treated animal model of AD, MSC administration significantly increased autophagosome induction, final maturation of late autophagic vacuoles, and fusion with lysosomes. Moreover, MSC administration significantly reduced the level of Aβ in the hippocampus, which was elevated in Aβ-treated mice, concomitant with increased survival of hippocampal neurons. Finally, MSC treatment up-regulated Beclin-1 expression in Aβ-treated cells and animals. These results suggest that MSC treatment significantly enhances autophagolysosome formation and clearance of Aβ in Aβ-treated cellular and animal models, which may lead to increased neuronal survival against Aβ toxicity. Modulation of the autophagy pathway to repair the damaged AD brain using MSCs would have a significant impact on future strategies for AD treatment.

Title: Enhancing the lysosomal degradation pathway promotes clearance of Aβ42 and α-synuclein in transgenic mouse models

Authors: U. S. IKONNE, J. HWANG, *B. A. BAHR;
Biotech. Res. and Training Ctr., Biotech Ctr. / William C. Friday Lab., Pembroke, NC

Abstract: Alzheimer's disease (AD) is the most frequent form of dementia and a key pathogenic factor is Aβ42 which accumulates as a result of over-production and/or inefficient clearance. The lysosomal enzyme cathepsin B (CatB) degrades Aβ42 by C-terminal truncation, lowering levels in mice expressing hAPP (Mueller-Steiner et al. 2006, *Neuron* 51:703; Butler et al. 2011, *PLoS One* 6:e20501; Wang et al. 2012, JBC 287:39834) and reducing both plaque load and behavioral and synaptic marker deficits. Accordingly, enhancing CatB is a promising drug discovery avenue for AD (Viswanathan et al. 2012, *ACS Med Chem Lett* 3:920), and studies suggest that lysosomal enhancement is also a potential strategy to reduce α-synuclein oligomers to treat Parkinson's disease (Lee et al. *J Neurosci* 24:1888). Here, the small-molecule CatB enhancing agent Z-Phe-Ala-diazomethylketone (PADK, 20 mg/kg/d i.p.) treated both 20-month APPswe/PS1ΔE9 mice and 8-month human α-synuclein A53T mice for 10-11 days, resulting
in a 4-8-fold increase in active CatB levels in brain samples as compared to vehicle-treated groups. In the APP-PS1 mice, the lysosomal enhancement was associated with a 62% reduction in Aβx-42 ELISA measures in hippocampal samples ($p<0.01$), and the 4-kDa band on 6E10 blots was also reduced by 60%. Synaptic marker deficits in the AD mice including GluR1, synapsin II, and NCAM180 exhibited
recovery in correspondence with the Aβ42 clearance. Recovered GluR1 levels correlated significantly with the extent of CatB enhancement. To test for α-synuclein clearance, PADK-treated A53T mice were assessed using TX-100 extractions. Similar to the effects on Aβ42, the PADK effect consisted of 50-70% declines in α-synuclein across spinal cord, brainstem, midbrain, and hippocampal samples ($p<0.01$). As in the AD tg mice, synaptic protection was also linked to the protein clearance. In fact, α-synuclein reduction across samples had a significant correlation with the extent of synaptic marker recovery. These
results indicate a single strategy can act against distinct protein accumulation events, promoting CatB-mediated protein clearance for disease-modifying treatments of early/progressive synaptic

decline and concomitant dementia. Contributing to the protective clearance, the CatB modulator PADK also has the ability to disaggregate Aβ42 oligomers (Zheng et al. 2012, *JBC* 287:6084), thus a role in oligomeric disaggregation may also lead to efficient uptake of diverse monomers and oligomers into neurons and microglia, thereby allowing trafficking to lysosomes for proteolytic detoxification.

Title: Copper lowering therapy for Alzheimer's disease

Authors: *K. VOSS, C. HARRIS, J. QUINN;
Neurol., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Background: Work from our lab and others has shown that high levels of copper in the brain of AD mouse models result in defects in learning and memory, increased aggregation of amyloid beta. Further, increased copper levels in AD mouse models can affect the hyperphosphorylation of tau protein.
Methods: Our lab is interested in determining if intake of oral zinc acetate, as a copper lowering therapy, is a viable strategy to reduce the effects seen in copper loaded AD mouse models. The use of zinc acetate is an FDA approved therapy for Wilson's disease, a genetic disorder that leads to increased copper accumulation in multiple organs including the brain. We tested this treatment in multiple AD mouse models, namely the Tg2576, 3xTg and hTau lines, which over express APPswe, APP/PS1/P301L tau, and wild-type human tau respectively.
Results: When oral zinc acetate is given to the mice, brain copper levels are reduced in all lines, indicating the treatment is not genotype specific. Our results also showed improvement in behavior and reduced amyloid beta load if treatment was begun early, but no effects if treatment was begun late. These data recapitulate results from our lab where copper lowering treatment

with tetrathiomolybdate improved AD like symptoms in mice if used as a preventative, but not as a treatment. We also saw modest effects on tau phosphorylation and processing in our 3xTg mice, and changes to plaque load as well. Zinc acetate had no effect on hTau mouse behavior, however, we found treatment caused a decrease in the amount of AT8 and AT180 positive tau in males, indicating a potential amyloid beta independent effect of copper loading on tau. Conclusions: These data suggest that reduction of brain copper may be a viable strategy for halting the progression of AD, through the reduction of phosphorylated tau and amyloid beta levels. If begun early enough, the treatment could have beneficial effects on the progression of the disease.

Title: Pharmacological inhibition of BACE1 interferes with synaptic plasticity

Authors: *S. FILSER[1], C. K. E. JUNG[1], S. V. OVSEPIAN[1], A. B. ELVANG[2], C. VOLBRACHT[2], J. HERMS[1];
[1]DZNE, Munich, Germany; [2]Lundbeck, Kopenhagen, Denmark

Abstract: Alzheimer disease is the most common cause of dementia in the elderly with currently no therapies or proven prevention methods available. Intervening with the proteolytic generation of the amyloid-β peptide, which is believed to be the trigger of the disease, is therefore a highly aspired strategy. We analysed the effects of prolonged oral treatment of adult mice with two novel, brain-penetrant inhibitors of BACE1 - a key enzyme in the generation of amyloid-β. Both inhibitors efficiently decreased amyloid-β 1-40 levels in the cortex and plasma but caused a precarious synaptic side effect. Utilizing in vivo two-photon microscopy, we discovered a dramatic reduction in the formation of new dendritic spines in the somatosensory cortex during the inhibition of BACE1 activity; an effect which rapidly reversed after treatment was stopped. Ex vivo patch clamp analysis in pyramidal neurons of the somatosensory cortex revealed a strong reduction in the frequency of spike-driven and miniature spontaneous EPSCs. Likewise, evoked field potentials in the hippocampal CA1 area exhibited a significant reduction in the strength and activity dependent long-term synaptic plasticity of these glutamatergic inputs. Overall, while our data demonstrate the essential role of BACE1 in synaptic plasticity in various

brain areas, they also raise concerns about potential side effects caused by the therapeutic inhibition of BACE1 for Alzheimer disease.

Abstract: Because metals are involved in amyloid pathogenesis by facilitating amyloid-β (Aβ) aggregation or deposition, metal-chelator or metal-Aβ interaction blocker is considered therapeutic candidate for Alzheimer's disease (AD). A small molecule L2-b [N^1,N^1-dimethyl-N^4-(pyridin-2-ylmethyl)benzene-1,4-diamine], which interacts with both metal ions and Aβ species, can dissolve metal-induced Aβ aggregation and attenuate neurotoxicity in vitro condition (Choi et al., 2010). In this animal study using a human amyloid precursor protein (hAPP)-overexpressing 5×FAD mice, we evaluated the activity of L2-b to arrest amyloid pathology. L2-b was administered into the peritoneum of the mice every day for 21 days. Histochemical analysis using Congo-red staining or APP/Aβ-specific antibodies showed that the treatments led to the reduced load of amyloid plaques in the brain compared to vehicle-treatment. Enzyme linked immunosorbent assays (ELISAs) revealed the significant reductions in soluble and insoluble Aβ40/42 contents of the brain. Currently, we are evaluating the beneficial activity of L2-b treatments to improve the behavior or cognitive activity in 5×FAD mice.

Abstract: Alzheimer's disease (AD) is the most common dementia and is a growing worldwide public health concern. AD neuropathological hallmarks include extracellular deposits of amyloid-β (Aβ) peptides, intracellular neurofibrillary tangles, neuronal and synaptic degeneration and loss, and neuroinflammation. Unfortunately, increasing numbers of AD pharmacotherapeutic agents have been abandoned worldwide due to toxicity issues or poor efficacy in pre-clinical rodent models and in the clinic. In this study, we tested whether the experimental agent methylene blue (MB), used for treatment of methemoglobinemia, might have anti amyloidogenic properties *in vivo*. We orally administered MB to the transgenic PSAPP mouse model of cerebral amyloidosis and evaluated cognitive function and cerebral amyloidosis. Beginning at 15 months of age, animals were gavaged with MB (3 mg/kg) or vehicle once daily for 3 months. MB treatment significantly prevented transgene-associated behavioral impairment including hyperactivity, decreased object recognition, and defective spatial reference memory, but did not alter non-transgenic mouse behavior. Moreover, brain parenchymal β-amyloid deposits and abundance of various Aβ species including oligomers were mitigated in MB-treated PSAPP mice. These effects occurred with a shift toward non-amyloidogenic amyloid precursor protein (APP) proteolysis. Specifically, we observed decreased cleavage of the β-carboxyl-terminal APP fragment and reduced β-site APP cleaving enzyme 1 protein expression and activity. These results raise the possibility that oral MB treatment may be a promising prophylaxis for AD-related cerebral amyloidosis by endorsing the anti-amyloidogenic pathway.

Title: L-3-n-butylphthalide improves cognitive impairment in a transgenic ad mouse model

Authors: *Y. PENG, Y. HU, S. XU, J. LI, L. WANG, X. WANG;
Inst. of Materia Medica, Beijing, China

Abstract: Alzheimer’s disease (AD) is an age-related and irreversibly progressive neurodegenerative disorder that occurs gradually and results in memory, behavior and personality changes. L-3-n-butylphthalide (L-NBP), an extract from seeds of *Apium graveolens Linn* (Chinese celery), has been demonstrated to have neuroprotective effects on ischemic, vascular dementia and amyloid-ß (Aß)-infused animal models by inhibiting oxidative injury, neuronal apoptosis and glial activation, regulating APP processing and reducing Aß generation. In the current study, we examine the effect of L-NBP on learning and memory in amyloid precursor protein (APP) and presenilin 1 (PS1) double-transgenic AD mouse model (APP/PS1) and the mechanisms of L-NBP in reducing Aß accumulation and tau phosphorylation. Twelve-month old APP/PS1 mice were given 15 mg/kg L-NBP by oral gavage for 3 months. L-NBP treatment significantly improved the spatial learning and memory deficits compared to the vehicle-treated APP/PS1 mice, whereas L-NBP treatment had no effect on cerebral Aß plaque deposition and Aß levels in brain homogenates. However, we found a L-NBP-induced reduction of tau hyperphosphorylation at Ser199, Thr205, Ser396 and Ser404 sites in APP/PS1 mice. At the meantime, the expressions of cyclin-dependent kinase (CDK-5) and glycogen synthase kinase 3ß (GSK-3ß), the most important kinases involved in tau phosphorylation, were markedly decreased by L-NBP treatment. The effects of L-NBP on decreasing tau phosphorylation and kinases activations were further confirmed in neuroblastoma SK-N-SH cells over-expressing WT human APP_{695} (SK-N-SH APPwt). L-NBP shows promising candidate of multi-target neuronal protective agent for the treatment of Alzheimer’s disease.

Title: Subchronic donepezil prevents amyloid-beta-induced memory disruption in the rat

Authors: *S. WAGNER, E. POIRAUD, N. KADOUCI, E. ANDRIAMBELOSON; NEUROFIT, ILLKIRCH, France

Abstract: Clinical studies have shown that donepezil potentially impacts the pathophysiology of Alzheimers's disease. In the present study, the neuroprotective effect of donepezil against amyloid-beta-induced memory dysfunction was investigated in the rat. Amyloid-beta (15 µg/rat) was stereotactically injected intracerebroventricular (i.c.v.) in male Wistar rats. After 2 weeks, memory performance was assessed using the passive avoidance test.
Subchronic donepezil (0.3 mg/kg/d) significantly reduced the number of trials to acquisition and prevented passive avoidance disruption in i.c.v. amyloid-beta injected rats. In contrast, acute donepezil (0.3 mg/kg) administered 30min prior the passive avoidance test did not modify the number of trials to acquisition and did not prevent passive avoidance disruption of i.c.v. amyloid-beta injected rats. It is noteworthy that acute donepezil significantly improved the memory performance of naïve rats as assessed in the passive avoidance test. The above findings suggest that subchronic donepezil interfered with the process of amyloid-beta -induced memory disruption in the rat. This beneficial effect of donepezil appeared unrelated to its acute cognitive enhancing property.

Title: Therapeutic effect of cholinesterase inhibitors rivastigmine, donepezil and tacrine on cognitive deficit induced by 3-quinuclidinyl benzilate in rats performing passive avoidance test

Authors: *J. MISIK[1], K. MUSILEK[2], K. KUCA[2], J. KASSA[2], O. SOUKUP[3];
[1]department of Toxicology, Fac. of Military Hlth. Sci., Czech Republic; [2]Dept. of Toxicology, Fac. of Military Hlth. Sci., Hradec Kralove, Czech Republic; [3]Ctr. of biomedical research, Univ. Hosp., Hradec Kralove, Czech Republic

Abstract: The central cholinergic system is significantly linked with tasks of learning and memory. A shortage of cholinergic transmission is connected with cognitive alterations, a typical sign accompanying neurodegenerative diseases. Cholinesterase inhibitors, considered for the palliative treatment of patients suffering from Alzheimer's disease, were tested for their efficacy in the treatment of experimentally induced cholinergic depletion. The aim of this study was to compare the therapeutic effect of inhibitors tacrine, rivastigmine and donepezil on cognitive impairment induced by cholinergic antagonist 3-quinuclidinyl benzilate (QNB) in rats. Male Wistar rats were divided into groups per 8 and subjected to the step-through passive avoidance task with one training session and a test session after 24 hours. Rats were administered with 2 $mg.kg^{-1}$ QNB intraperitoneally before training session (30 min), followed by therapeutic dose of tacrine (3.0 and 6.0 $mg.kg^{-1}$) rivastigmine (0.6 and 1.2 $mg.kg^{-1}$) or donepezil (0.75 and 2.65 $mg.kg^{-1}$) in 15 minutes. The therapeutic doses were responsible for inhibition of brain cholinesterase in the range of 10 - 40 %. The retention entrance latency of rats treated with inhibitory drugs were compared to that of non-treated, which were administered with QNB followed by saline instead of inhibitory drug and blank controls, treated with saline instead of both, QNB and a drug. QNB significantly impaired the behavioral response of rats - QNB-administered rats showed shorter test entrance latency than control rats (Kruskal-Wallis test, $p< 0.001$). When treated, the retention latency was significantly improved in both rivastigmine-treated groups ($p < 0.05$) corresponding to cholinesterase inhibition 10 and 40%, respectively. There was no curative effect in both donepezil-treated groups and tacrine-treated groups at tested doses. Moreover, 2 out of 8 tacrine-treated rats showed signs of cholinergic over-stimulation at the higher dose of tacrine (6 $mg.kg^{-1}$). In summary, rivastigmine at the dose of 0.6 $mg.kg^{-1}$ was the most effective in reversion of QNB-induced behavioural deficit.

Title: Effects of caffeine intake and adenosine A2A receptor deletion in a transgenic model of Alzheimer's Disease-like Tau pathology

Authors: *D. BLUM[1], C. LAURENT[1], S. BURNOUF[1], B. FERRY[2], E. MARCINIAK[1], M. DERISBOURG[1], S. EDDARKAOUI[1], S. PARROT[2], D. DEMEYER[1], C. LEDENT[3], C. MÜLLER[4], N. SERGEANT[4], M. HAMDANE[4], S. HUMEZ[1], L. LOPES[5], L. BUEE[1]; [1]Inserm U837, Alzheimer & Tauopathies, Lille, France; [2]Inserm U1028, Ctr. de Recherche en Neurosciences, Lyon, France; [3]IRIBHM, Brussels, Belgium; [4]Pharmaceut. Institute, Univ. of Bonn, Bonn, Germany; [5]Inst. de Medicina Molecular, Faculdade de Medicina de Lisboa, Lisbon, Portugal

Abstract: Alzheimer’s disease (AD) is characterized by extracellular amyloid deposits and intraneuronal neurofibrillary tangles, made of aggregated hyper- and abnormally phosphorylated Tau proteins. The latter, referred to as “Tau pathology”, contribute to synaptic impairments leading to memory deficits in AD patients. Previous epidemiological studies revealed that habitual caffeine consumption reduces the risk to develop AD. Experimental studies suggested that chronic caffeine treatment mitigates spatial memory impairments and Aβ load in APP transgenic mice. Further, caffeine was also shown to reduce Aβ neurotoxicity, through A2A-receptor blockade. However, effects of caffeine and A2A receptor blockade towards Tau pathology remains unknown so far. The present study was aimed at evaluating the impact of chronic caffeine intake and A2A receptors deletion on memory deficits and neuro-inflammatory processes in a transgenic mouse model (THY-Tau22) exhibiting progressive hippocampal Tau pathology.

Caffeine (0.3g/L) was chronically administered through drinking water to Tau mice and littermate controls from 2 to 12 months of age. At completion of the treatment, caffeine was readily detected in the brain and plasma of treated animals. Results showed that caffeine treatment improved spatial memory in THY-Tau22 mice. That was associated with reduced Tau phosphorylation and proteolysis. Further, caffeine treatment significantly reduced hippocampal neuro-inflammation as shown by the reduction of several pro-inflammatory markers previously found overexpressed in THY-Tau22 mice. Effects of caffeine were partly mimicked by A2A receptor deletion. Indeed, loss of A2A receptors prevented Tau-dependent spatial memory alterations, an effect associated with a normalization of the hippocampal Glutamate/GABA ratio as seen obtained using microdialysis technique. Further, A2A receptor deletion led to a significant reduction of hippocampal Tau phosphorylation. Finally, THY-Tau22 A2A KO mice exhibited reduced hippocampal neuro-inflammation. Altogether, the present data are the first reporting that caffeine intake and A2A receptor deletion exert beneficial effect in a Tau transgenic mouse model of AD. These data support the therapeutic potential of both caffeine and A2A receptor antagonists in AD.

Title: Intravenous neprilysin reduces peripheral Aβ in mouse but does not correlate with brain amyloid burden

Authors: *A. M. SCHUMACHER[1,2], R. PACOMA[2], J. WATSON[2], W. OU[2], J. ALVES[2], D. E. MASON[2], E. C. PETERS[2], H. D. URBINA[2], G. WELZEL[2], A. ALTHAGE[2], B. LIU[2], T. TUNTLAND[2], L. H. JACOBSON[3], J. L. HARRIS[2], J. R. WALKER[2];
[1]Novartis, SAN DIEGO, CA; [2]Genomics Inst. of the Novartis Res. Fndn., San diego, CA; [3]Novartis Inst. for Biomed. Res., Basel, Switzerland

Abstract: Pathological aggregation and buildup of beta-amyloid (Aβ) in the brain is a hallmark of Alzheimer’s Disease (AD). Aβ levels are regulated by production from the

amyloid precursor protein, proteolytic degradation, and peripheral clearance. In this study we investigated whether enhancing clearance of plasma Aβ via peripheral administration of the Aβ-degrading protease neprilysin (NEP) would reduce brain Aβ levels through a peripheral sink. We developed an Fc-NEP fusion protein that demonstrated *in vitro* degradation of Aβ and a 10 day plasma half-life in mouse. Intravenous delivery of this active NEP protein to WT and APP23 transgenic mice resulted in a dose-dependent reduction of plasma Aβ. However, this did not correspond to a reduction in the levels of soluble brain Aβ with treatment up to 5 weeks in WT mice or formic acid-extractable brain Aβ with 3 month treatment in aged APP23. In contrast, direct intracranial injection of the Fc-NEP resulted in an acute decrease in soluble brain Aβ. These results suggest a lack of a robust peripheral Aβ efflux sink through which brain amyloid burden can be therapeutically reduced.

Title: Centella asiatica protects against the toxic effects of intracellular β-amyloid accumulation

Authors: ***N. E. GRAY**[1], J. MORRE[2], J. KELLEY[2], C. S. MAIER[2], J. F. STEVENS[2], A. SOUMYANATH[1], J. F. QUINN[1];
[1]Oregon Hlth. and Sci. Univ., Portland, OR; [2]Oregon State Univ., Corvallis, OR

Abstract: Background: The plant *Centella asiatica* has been used in Ayurvedic medicine as a nerve tonic and to enhance cognition, effects that have been confirmed experimentally in animals as well as human subjects. Previous research in our lab has shown that the water extract of *Centella asiatica* (CAW) corrects beta amyloid (Aβ)- induced cognitive deficits in a transgenic model of Alzheimer's disease and prevents Aβ toxicity *in vitro*. In this study we evaluate the effects of CAW on Aβ-induced alterations in neuroblastoma cells and identify potentially active compounds within the extract.
Methods: Using the MC65 neuroblastoma cell line, a model of intracellular Aβ toxicity, we evaluated the effects of CAW cell viability, Aβ expression, tau expression and phosphorylation and induction of the antioxidant response gene NRF2 (nuclear factor erythroid-derived factor 2). We also used high-resolution mass spectrometry (HRMS) and high performance liquid chromatography (HPLC) to identify compounds present in the CAW extract.
Results: CAW treatment reduced Aβ-induced cell death without changing Aβ accumulation in the cells. Additionally, CAW attenuated Aβ-induced increases in total tau expression and site specific phosphorylation of tau. CAW also robustly increased expression of NRF2 as well as its target genes.
HPLC analysis revealed that the triterpene compounds, asiatic acid, madecassic acid, asiaticoside and madecassoside, found in the plant and reported to have potent biological activities, were absent in CAW. Instead, using HRMS several caffeoylquinic acids and derivatives were determined to be present in CAW.
Discussion: Our data show a protective effect of CAW on Aβ-induced toxicity in MC65 cells. CAW prevented cell death, normalized tau expression and phosphorylation and induced expression of NRF2 and its target genes. While more studies are needed to confirm mechanisms, the effects on NRF2 suggests that the protective effect of CAW could be due, at least in part, to antioxidant actions. Additionally, the ability of CAW to prevent Aβ-induced cell death without altering overall Aβ accumulation suggests that its action is downstream of Aβ oligimerization, a potentially novel and clinically relevant mechanism of action.
Our chemical analysis also identified several caffeoylquinic acid compounds were present in CAW. This class of compounds has been shown to have neuroprotective effects against exogenous Aβ administration and to induce antioxidant response genes, therefore it is possible they are the active constituents in CAW. Studies are currently underway to determine the efficacy of these compounds in the MC65 model system.

Title: The histamine H3 receptor antagonist SAR110894D prevents the development of Tau neurofibrillary tangles and improves cognitive deficits in a mouse model of tauopathy

Authors: J. STEMMELIN[1], V. BLANCHARD[1], N. SCHUSSLER[1], M. LOPEZ-GRANCHA[1], J. MENAGER[1], V. MARY[1], P. DELAY-GOYET[1], *G. A. BOHME[2], T. ROONEY[1], L. PRADIER[1], J. J. ALAM[1], S. CLAUDEL[1], P. BARNEOUD[1];
[1]Sanofi Resarch & Develop., Chilly-Mazarin, France; [2]TSU Aging, Project leader, Sanofi-Aventis Resarch & Develop., Chilly-Mazarin, France

Abstract: SAR110894D is a selective histamine H3 receptor (H3R) antagonist with sub-nanomolar affinity for human and rodent H3Rs and pro-cognitive activity in vivo[1]. Although H3R antagonists have been initially positioned as a treatment for the cognitive symptoms of Alzheimer's disease through enhancement of neurotransmitter release, recent data have highlighted their potential to decrease tau phosphorylation in animal models. In the present study we have examined the effect of SAR110894D on tau hyperphosphorylation and the formation of neurofibrillary tangles (NFTs) in a tau transgenic mouse model (THY-Tau22) which selectively overexpresses human 4-repeat tau (with double G272V/P301S mutations) in brain neurons and displays age-dependent tau pathology. SAR110894D was evaluated by using preventive (2 weeks or 6 months treatment starting at 2.5-3 months of age) treatment paradigm in Tau-22 mice. SAR110894D (0.002 and 0.02% in drinking water eq. 1-10mg/kg/d o.d.) had no effect on tau hyperphosphorylation at pSer199-202/Thr205 (AT8 epitope) and did not increase Ser9-GSK3β phosphorylation in the cortex of 3 month-old mice after 2 weeks treatment. By contrast, when 2.5 month old mice were treated with SAR110894D (0.00034%, 0.0034% and 0.034% in food, eq. 0.1-1-10mg/kg/d, o.d.) for 6 months, SAR110894D decreased both tau hyperphosphorylation at pSer396-pSer404 (AD-2, -37% @ 0.0034%) and pSer199-202/Thr205 (AT8, -47% @ 0.0034%) in the cortex and the formation of NFTs (Gallyas staining) in the cortex (-48% @ 0.0034%), hippocampus (-25% @ 0.0034%) and amygdala (-31% @ 0.034%). Ser9-GSK3β phosphorylation was not modified at any doses tested. Moreover, SAR110894D (0.00034%, 0.0034%) decreased the expression of macrophage inflammatory protein (MIP)-1α mRNA (a marker of microgliosis) in the hippocampus by 35% and 36%, respectively. In addition, SAR110894D improved episodic shape and spatial memory deficits in THY-Tau22 mice after 6 months of treatment. These results demonstrate that SAR110894D prevents tau hyperphosphorylation and the formation of NFTs after chronic, but not acute, treatment and suggest that long term SAR110894D treatment could have potential disease modifying activity in Alzheimer's disease.

Title: Mesenchymal stem cells increase hippocampal neurogenesis and neuronal differentiation by enhancing the Wnt signaling pathway in Alzheimer’s disease model

Authors: *H. PARK;
Neurol., Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: ABSTRACT
Neurogenesis in the subgranular zone (SGZ) of the hippocampal dentate gyrus may act as an endogenous repair mechanism in Alzheimer’s disease (AD) and the Wnt signaling pathway has been suggested to closely modulate neurogenesis in amyloid-β (Aβ)-related AD models. The present study investigated whether mesenchymal stem cells (MSCs) would modulate hippocampal neurogenesis via modulation of the Wnt signaling pathway in a model of AD. In Aβ-treated neural progenitor cells (NPCs), the co-culture with MSCs increased significantly the expression of GFAP, SOX2, and HuD compared to Aβ treatment alone. In addition, MSC treatment in Aβ-treated NPCs enhanced the expression of Wnt3a, β-catenin, and Ngn1 compared to Aβ treatment alone. MSC treatment in Aβ-treated animals significantly increased the number of BrdU-ir cells in the hippocampus at 2 and 4 weeks compared to Aβ treatment alone. In addition, quantitative analysis showed that the number of BrdU and HuD double-positive cells in the dentate gyrus was significantly higher in the MSC-treated group than in controls or after Aβ treatment alone. These results demonstrate that MSC administration significantly augments hippocampal neurogenesis and enhances the differentiation of NPCs into mature neurons in AD

models by augmenting the Wnt signaling pathway. The use of MSCs to modulate endogenous adult neurogenesis may have a significant impact on future strategies for AD treatment.

Abstract: Background:
Amyloid-beta (Aβ) fibril-containing amyloid plaques in the brain are a hallmark of Alzheimer's disease (AD) but a recent paradigm shift indicates Aβ oligomers as crucial neuropathogenic agents in AD. Using an *in vitro* generated Aβ oligomer, the truncated Aβ(20-42) Globulomer (tAβ Globulomer), we generated a humanized, Aβ oligomer-specific antibody, ABT-736 for use in passive immunotherapy of AD. ABT-736 selectively detects Aβ oligomers in the brains of AD patients, APP Tg-mice and in vitro. The tAβ Globulomer itself is also an ideal antigen for active immunotherapy of AD as the elicited immune response is Aβ oligomer selective.
Here, we show the efficacy of tAβ Globulomer immunization in reducing Aβ oligomer levels in Tg2576 mice and the favorable pharmacokinetic profile of ABT-736 due to its high Aβ oligomer selectivity.
Results:
ABT-736 in cynomolgus monkeys (single dose, 5 mg/kg, IV or SC) exhibited a favorable pharmacokinetic profile, including long serum half-life of 7.5 - 9 days (SC / IV respectively) of the free antibody.
To demonstrate the specificity of ABT-736, anti-Aβ antibodies were injected 2h prior to following the plasma clearance of injected 125Iodine-Aβ1-40 in APP/Lo mice. A pan Aβ antibody prevented the rapid clearance of 125I-Aβ1-40. In contrast, ABT-736 that does not bind

to monomeric Aβ *in vivo* did not impact the elimination of the peptide, it was as efficiently cleared from blood as in the presence of an unspecific IgG antibody.
For active tAβ Globulomer immunization we used Tg2576 mice (3 month). At 12 month age without any further boosting tAβ Globulomer titers were ~ 1:200-4000. This titer proved sufficient to reduce Aβ oligomer levels in the hippocampus by 50% (p=0.01) compared to control mice.
Conclusion:
We propose that exclusively targeting Aβ oligomers as neuropathogenic agents of AD with Aβ oligomer selective antibodies like ABT-736 or an active tAβ Globulomer immunotherapy has major advantages.
The high selectivity of ABT-736 for Aβ oligomers eliminates its binding to, and hence its consumption by, other non-disease related Aβ species, such as Aβ monomers, sAPPα, Aβ fibrils. This selectivity, firstly reduces potential side effects and secondly results in a favorable PK profile of ABT-736. In summary, these characteristics provide passive ABT-736 or active tAβ Globulomer immunotherapy with a highly favorable profile compared to Aβ peptide unselective immunotherapy for AD.

Title: A lipoprotein receptor cluster IV mutant preferentially binds amyloid-β and regulates its clearance from the mouse brain

Authors: *A. P. SAGARE[1], R. D. BELL[2], A. SRIVASTAVA[3], J. D. SENGILLO[1], I. SINGH[2], Y. NISHIDA[2], N. CHOW[3], B. V. ZLOKOVIC[1];

Abstract:
Soluble low-density lipoprotein receptor-related protein-1 (sLRP1) binds ~ 70% of amyloid β-peptide (Aβ) in human plasma. In Alzheimer's disease (AD) and individuals with mild cognitive impairment converting to AD, plasma sLRP1 levels are reduced and sLRP1 is oxidized which results in diminished Aβ peripheral binding and higher levels of free Aβ in plasma. Experimental studies have shown that free circulating Aβ re-enters the brain and that sLRP1 and/or its recombinant wild-type cluster IV (WT-LRPIV) prevent Aβ from entering the brain. Treatment of Alzheimer's *APPsw*$^{+/0}$ mice with WT-LRPIV has been shown to reduce brain Aβ pathology. In addition to Aβ, LRPIV binds multiple ligands. To enhance LRPIV binding for Aβ relative to other LRP1 ligands, we generated a library of LRPIV-derived fragments and full-length LRPIV variants with glycine (G) replacing aspartic acid (D) residues 3394, 3556 and 3674 in the calcium binding sites. Compared to WT-LRPIV, a lead LRPIV-D3674G mutant had 1.6-fold and 2.7-fold higher binding affinity for Aβ40 and Aβ42 *in vitro*, respectively, and a lower binding affinity for other LRP1 ligands, e.g., apoliporotein E2, E3 and E4 (1.3-1.8-fold), tissue plasminogen activator (2.7-fold), matrix metalloproteinase-9 (4.1-fold) and Factor Xa (3.8-fold). LRPIV-D3674G cleared mouse endogenous brain Aβ40 and Aβ42 25-27% better than WT-LRPIV. A 3-month subcutaneous treatment of *APPsw*$^{+/0}$ mice with LRPIV-D3674G (40 μg/kg/day) reduced Aβ40 and Aβ42 levels in the hippocampus, cortex and cerebrospinal fluid by 60-80%, and improved cerebral blood flow responses and hippocampal function at 9 months of age. Thus, LRPIV-D3674G is an efficient new Aβ clearance therapy.

Title: AAV-mediated delivery of apoE2 to reduce AD neuropathology in transgenic mice

Authors: *L. ZHAO[1], A. J. GOTTESDIENER[1], M. LI[3], C. M. GREVSTAD[1], S. M. KAMINSKY[2], M. J. CHIUCHIOLO[2], D. SONDHI[2], R. G. CRYSTAL[2], S. M. PAUL[1]; [1]Appel Alzheimer's Dis. Res. Institute, Mind and Brain Res. Inst., [2]Dept. of Genet. Med., Weill Cornell Med. Col., New York, NY; [3]Dept. of Neurol. and Hope Ctr. for Neurolog. Disorders, Washington Univ. Sch. of Med., St. Louis, MO

Abstract: The common apolipoprotein E (*APOE*) alleles are important genetic risk factors for late-onset Alzheimer’s disease (AD). *APOE*4 carriers have a markedly increased risk for developing AD (3-15 fold for heterozygotes and homozygotes respectively) whereas *APOE*2 is protective, reducing AD risk by 50% and markedly delaying the age of onset. We have previously reported that gene delivery of apoE2 using a lentiviral vector directly into the hippocampus of mutant amyloid precursor protein (APP) transgenic mice, decreases hippocampal Aβ levels and amyloid burden. Adeno-associated virus (AAV) vectors have demonstrated the capacity for robust and persistent gene expression in the central nervous system (CNS). To further explore gene delivery of apoE2 as a therapeutic strategy for AD, we compared several AAV serotypes for apoE2 expression in the CNS and evaluated changes in amyloid pathology in a transgenic amyloid-depositing mouse model of AD. We first compared expression of the apoE2 gene in apoE knock-out (EKO) mice mediated by each of several AAV serotypes, promoters and routes of delivery. We found that AAV8, AAV9 and AAVrh.10 mediate efficient apoE2 expression in brain, and the astrocytic promoter for glia fibrillary acidic protein (GFAP) results in astrocyte-specific expression of apoE2 at physiological levels. By contrast, AAV serotype vectors with the constitutive CBA promoter result in 5-6 times higher levels of apoE2

expression in brain. We next injected AAV8-GFAP-apoE2 or AAVrh.10-CBA-apoE2 into the hippocampus of 9-month old PDAPP transgenic mice. After 8 weeks, AAVrh.10-CBA-apoE2 treatment resulted in a marked decrease in both soluble (~33% reduction. $p < 0.05$) and insoluble Aβ1-42 levels (~70% reduction. $p < 0.001$) compared to control mice. In contrast, AAV8-GFAP-apoE2 treatment resulted in only a modest reduction of soluble Aβ1-42 (17% reduction. $p < 0.05$). Our data extends our earlier findings using lentiviral-mediated gene delivery of apoE2 and suggest that supraphysiological levels of apoE2 may be essential to reduce brain amyloid burden in mice with existing substantial Aβ/amyloid deposition. Further characterization of the effects of AAV-apoE2 on brain AD pathology in transgenic mice of different ages may help to elucidate whether apoE2 gene delivery represents a potential therapeutic intervention for either preventing or treating AD.

Title: Activation of β1-adrenergic receptor rescues social memory deficit in the mouse model of Alzheimer’s disease

Authors: *P. MEMAR ARDESTANI, L. COUTELLIER, M. SHAMLOO;
Stanford Univ., Palo Alto, CA

Abstract: Impaired social recognition is seen in many neurodegenerative disorders. Investigating neural basis of such defects may provide insight to the underlying mechanisms of these disorders and highlight new therapeutic approaches.
In this study, we used the Thy1-APPLond/Swe (APP) mice model of Alzheimer’s disease (AD). We show that these mice display social recognition impairments without any impairment in olfactory abilities. Due to progressive degeneration of noradrenergic system in AD and according to our new findings on the role of β1-adrenergic activation in medial amygdala (MeA) is key for social recognition, we investigated if this receptor could be targeted in experimental

AD to rescue the social recognition deficit. We have shown that treatment with xamoterol, a β1-adrenergic receptor (β1-ADR) partial agonist, rescues the social deficit observed in APP mice. We hypothesized that alterations in the pCREB signaling pathway downstream of the B1-ADR could be responsible for this effect. In conclusion, our result suggest alteration of the B1-ADR/pCREB signaling cascade is responsible for the social memory deficit seen in AD and targeting this receptor can be a potential therapeutic approach to treat social abnormalities seen in AD patients.

Title: A pyrazole derivative of curcumin improved brain insulin resistance and cognitive decline in a transgenic mouse model of Alzheimer’s disease

Authors: *Q.-L. MA[1,2], X. ZUO[1,2], F. YANG[1,2], Q. CHEN[1,2], S. A. FRAUTSCHY[1,3], G. M. COLE[1];

Abstract: Growing evidence indicates that brain insulin resistance is a common and early molecular pathological feature of Alzheimer’s disease (AD) for which type II diabetes is an important risk factor. Talbot and colleagues have shown early stage AD brains have elevated

serine phosphorylation of IRS-1 corelating with its upstream activated Akt, GSK, ERK , JNK and mTOR. Our previous study reported that compared to normal control diet, feeding 3xTg-AD transgenic mice with a diet high in saturated and omega-6 fat induced significant degradation of IRS-1 that was consistently associated with basal elevation of hippocampal IRS-1 phosphorylated at serine 616 (IRS-1pS616), a key marker of insulin resistance in the periphery and AD brain. This phosphorylation was sensitive to two interventions that reduced active JNK (fish oil and curcumin). In this study, we used 3xTg-AD mice with features of basal brain insulin resistance, and treated with a pyrazole derivative of curcumin named CNB-001. This derivative has a better oral bioavailablity profile than curcumin and additional strong neuroprotective activities in models with excitotoxicity, oxidative damage and glucose starvation. We treated these mice for four-months which resulted in significant amelioration of markers related to brain insulin resistance including increases in total IRS-1 and decreases in IRS-1pS616. This was accompanied by improvement of working memory using spontaneous alteration in the Y-maze. CNB-001 also significantly lowed activated Akt, GSK-3, ERK, JNK and mammalian target of rapamycin (mTOR), which have been reported to exert feedback inhibition on insulin receptor beta and IRS-1 contributing to basal insulin resistance as measured in AD tissue and ex vivo AD brain samples. CNB-001 also reduced ptau. Our data demonstrate that dietary CNB-001 has the potential to improve insulin signaling and cognitive deficits in an AD animal model with both abeta and tau pathology and markers of basal insulin resistance resembling AD brain. Given CNB-001's other reported neuroprotective effects and the known role of the related kinase pathways in IRS-1 and tau molecular pathology as well as synaptic plasticity, CNB-001 and related compounds should be further explored as potential novel drugs for AD therapy that provide alternatives or adjuncts to simply targeting abeta.

Title: Development of novel *In vivo* molecular probes for CNS serine-threonine protein kinases that modulate synaptic dysfunction

Authors: O. ARANCIO[1], V. L. GRUM-TOKARS[2], S. M. ROY[2], J. P. SCHAVOCKY[2], B. BRADARIC[2], A. D. BACHSTETTER[3], B. XING[3], E. DIMAYUGA[3], F. SAEED[1], H. ZHANG[1], A. STANISZEWSKI[1], J. C. PELLETIER[2], G. MINASOV[2], W. F. ANDERSON[2], *L. J. VAN ELDIK[4], D. WATTERSON[2];

Abstract: Serine-threonine protein kinases are critical to CNS function, yet there is a dearth of highly selective, CNS-active kinase inhibitors for in vivo investigations. Further, prevailing assumptions raise concerns about whether single kinase inhibitors can show in vivo efficacy for CNS pathologies, and debates over viable approaches to the development of safe and efficacious kinase inhibitors are unsettled. It is critical, therefore, that these scientific challenges be addressed in order to test hypotheses about protein kinases in neuropathology progression and the potential for in vivo modulation of their catalytic activity. Identification of molecular targets whose in vivo modulation can attenuate synaptic dysfunction would provide a foundation for future disease-modifying therapeutic development as well as insight into cellular mechanisms. Clinical and preclinical studies suggest a critical link between synaptic dysfunction in neurodegenerative disorders and the activation of p38αMAPK mediated signaling cascades. Activation in both neurons and glia also offers the unusual potential to generate enhanced responses through targeting a single kinase in two distinct cell types involved in pathology progression. However, target validation has been limited by lack of highly selective inhibitors amenable to in vivo use in the CNS. Therefore, we employed high-resolution co-crystallography and pharmacoinformatics to design and develop a novel synthetic, active site targeted, CNS-active, p38αMAPK inhibitor (MW108). Selectivity was demonstrated by large-scale kinome screens, functional GPCR agonist and antagonist analyses of off-target potential, and evaluation of cellular target engagement and mechanism of action. In vitro and in vivo assays demonstrated that MW108 ameliorates beta-amyloid induced synaptic and cognitive dysfunction. A serendipitous discovery during co-crystallographic analyses revised prevailing models about active site targeting of inhibitors, providing insights that will facilitate future kinase inhibitor design. Overall, our studies deliver highly selective in vivo probes appropriate for CNS

investigations and demonstrate that modulation of p38αMAPK activity can attenuate synaptic dysfunction.

Title: Neuronal and astrocytic differentiation following transcranial focused ultrasound

Authors: *T. SCARCELLI[1], J. F. JORDAO[2], N. ELLENS[3], M. O'REILLY[3], K. HYNYNEN[3], I. AUBERT[2];
[1]Res., [2]Biol. Sci., [3]Physical Sci., Sunnybrook Res. Inst., Toronto, ON, Canada

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative disorder characterized by a deterioration in cognition and the development of pathological hallmarks, including amyloid-beta peptide (Aβ) aggregation and cell loss. MRI-guided focused ultrasound (MRIgFUS) can be used to locally and reversibly increase the permeability of the blood-brain barrier (BBB) and improve therapeutic efficacy by enhancing the delivery of anti-Aβ antibodies to the brain. Studies from our laboratory have shown that MRIgFUS-delivery of anti-Aβ antibodies (BAM10) significantly reduced Aβ plaque number, size and surface area by 4 days post-treatment in a mouse model of AD (Jordão et al., 2010). We recently found that MRIgFUS treatment in the absence of BAM10 also reduced Aβ plaque size and surface area after 4 days. Here, we examined whether MRIgFUS alone and in the combination with BAM10 results in Aβ reduction after 18 days. This decline in Aβ load could contribute to the enhanced survival and differentiation of newborn cells in the hippocampus, which were also examined in this study. Stereological and ImageJ analyses were used to quantify Aβ plaque number, size and surface area in the cortex and hippocampus. Immunohistochemistry and confocal microscopy were used to quantify the population of proliferating cells that survived and differentiated into neurons and

astrocytes, through the co-localization of cell lineage markers with the proliferation marker 5-bromo-2’-deoxyuridine at 18 days post-treatment. We found that MRIgFUS in the presence of 1mg/kg BAM10 significantly reduced Aβ surface area by 18 days post-treatment, potentially stimulating neuron and astrocyte proliferation and differentiation. To examine the effects of MRIgFUS treatment alone in the absence of Aβ accumulation, treatment was applied to non-transgenic mice. MRIgFUS up-regulated cell proliferation and survival in the hippocampus, leading to enhanced neuronal and astrocytic differentiation. Overall, this study showed that MRIgFUS enhances cell proliferation, differentiation and survival in the non-transgenic mice and that the addition of the anti-Aβ therapeutic may be needed to produce similar effects in the AD-like mouse model. MRIgFUS-delivered immunotherapy could then be used to decrease Aβ load and increase neuronal and astrocytic differentiation, providing a multifaceted approach to AD treatment.

Title: Neuroprotective effect of flavonoids in a triple transgenic alzheimer's disease mice model

Authors: *G. P. CARDONA GOMEZ, A. M. SABOGAL-GUÁQUETA, 1, J. MUÑOZ-MANCO, 2, N. CORTEZ-RENDÓN, 3, R. RAMIREZ-PINEDA, 4, E. OSORIO-DURANGO, 5; Univ. Antioquia, Medellin, Colombia

Abstract: Alzheimer's disease (AD) is the most common dementia in the world, which is characterized by progressive loss of cognitive functions. For this disease, palliative treatments have been proposed, which don´t prevent or reverse the progression of disease. In this study, we evaluated the neuroprotective effect of flavonoids: quercetin (Q) and Biflavonoid fraction (BF) extracted from Garcinia madruno (25 mg/kg) via ip, administered every 48 hours during 3 months in old mice (22 months) triple transgenic 3xTg-AD. The tasks of spatial learning and memory were analyzed by Morris water maze, besides neurodegeneration markers (Nissl, NeuN,

GFAP, Iba-1) and neuropathological (β-A (β-amyloid) and AT-8 (hyperphosphorylated tau), were evaluated by immunohistochemistry. Our data show that animals treated with flavonoids exhibit a significant reduction in β-A extracellular plaques, tauopathy, astrogliosis and morphological changes in microglia in regions involved in emotional and cognitive behavior as CA1 of hippocampus, the amygdala, the subiculum and in entorhinal cortex. These results were supported by biochemical findings with reduced AT-8 and reduced cleavage of APP by BACE1 (CTFβ), furthermore Q also reduced cleavage by α-secretase (CTFα). Additionally, both treatments induced a better performance in learning and spatial memory in comparison with controls (DMSO). Our data suggest that systemic administration of flavonoids have effects that reverse the main histological hallmarks and cognitive dysfunction in old mice 3xTg for Alzheimer's disease.

Title: The Ly-6 proteins prostate stem cell antigen (PSCA) and Ly6H are increased in frontal cortex in Alzheimer’s disease

Authors: *M. M. JENSEN, J. D. MIKKELSEN, M. S. THOMSEN;
Neurobio. Res. Unit, Copenhagen, Denmark

Abstract: Alzheimer’s disease (AD) is a neurodegenerative disorder, characterized by impaired cholinergic neurotransmission and altered expression and function of the most abundant subtypes of nicotinic acetylcholine receptors (nAChRs), the α7 and α4β2. These receptors are highly implicated in cognitive function and associated to the pathology of AD. However, studies on nAChR protein levels in AD have yielded inconsistent results with both down-regulation and no change having been reported. In recent years, interest in the α-bungarotoxin-like Ly-6 protein family has increased after the discovery that several members of the Ly-6 protein family bind to

and modulate the function of the nAChRs with an important impact on synaptic plasticity. Given the interaction between nAChRs and Ly-6 proteins, we here investigated whether Ly-6 proteins are altered in AD. We analyzed the protein levels of prostate stem cell antigen (PSCA), Ly6H, and Lypd6 in post-mortem tissue of medial frontal gyrus from non-demented controls (n=8) and AD (n=7) using western blotting. To further investigate a possible mechanism, we also analyzed the expression of the Ly-6 proteins in frontal cortex of transgenic Tg2576 mice over-expressing APP to see whether changes in Ly-6 protein levels are influenced by amyloid pathology.
We find that PSCA and Ly6H levels are significantly increased in AD patients (198±22%, $P<0.05$ and 214±38%, $P<0.01$, respectively), whereas Lypd6 levels are unchanged (99±10%, $P=0.93$). In Tg2576 mice no significant changes in PSCA and Lypd6 levels are observed (83±11%, $P=0.40$ and 102±4%, $P=0.66$, respectively), whereas Ly6H is decreased in the Tg2576 mice (75±7%, $P<0.05$) compared to wild-type.
Since PSCA is a negative modulator of the α7 nAChR, our results suggest that the function of α7 nAChRs may be decreased in AD. Thus, PSCA could be an alternative target in the treatment of AD, where current therapies have limited effects. It seems that increased APP expression is not driving the frontal cortex increase in PSCA and Ly6H found in patients with AD. Hence, other key features of AD pathology such as neurofibrillar tangles could be implicated.**Poster**

Title: Estrogen amelioration of Abeta induced defects in mitochondria is mediated by a signaling pathway involving Drp1,ER-beta, and AKAP

Authors: *S. N. SARKAR[1], J. W. SIMPKINS[2];
[1]PHYSIOLOGY AND PHARMACOLOGY, WEST VIRGINIA UNIVERSITY, MORGANTOWN, WV; [2]physiology and pharmacology, wvu, morgantown, WV

Abstract: Perturbations in dynamic properties of mitochondria, which include fission, fusion, trafficking and turnover, can lead to synaptic dysfunction, apoptosis and necroptosis, and are implicated as playing a crucial role in neurodegenerative diseases, including Alzheimer's (AD), Parkinson (PD), and Huntington (HD). It is established that accumulated Aβ in synaptic

mitochondria causes impairment of respiratory function, excessive fragmentation, and deceleration of movement. In addition, it has been shown that mitochondrial fission protein Drp1interacts with Aβ and phosphorylated tau in Alzheimer's disease neurons. Although, we are beginning to understand Aβ-induced mitochondrial defects that lead to synaptic damage and dysfunction, the molecular mechanisms underlying these defects are still unclear. Previously, we and others have shown that estrogen receptor β (ER-β) is localized in the mitochondria. Because selective ER-β modulator (DPN) can activate PKA, we reasoned that DPN- induced nongenomic ER-β signaling in the mitochondrial membrane could rescue many of the mitochondrial defects caused by soluble Aβ oligomer-induced inhibition of PKA signaling cascades. We now report that DPN treatment attenuates low-dose soluble Aβ-oligomer induced dendritic mitochondrial fragmentation and reduced mobility. Measurement of mitochondrial function reveals that Aβ treatment reduces the respiratory reserve capacity of hippocampal neuron and DPN treatment ameliorates this inhibition. Biochemical analysis shows that Aβ treatment inhibits phosphorylation of dynamin-related protein 1 (Drp1) at its PKA site, and DPN treatment ameliorates this inhibition. Further, we show that arginine methylation site spanning ERβ domain interacts with mitochondrial resident PKA-AKAP signaling complex. Taken together these results strongly indicate that ERβ binds to AKAP. Further, DPN ligand-ERβ-PKA-AKAP interaction induced signaling phosphorylate Drp1 mediated attenuation of Aβ inhibition of dynamic properties of mitochondria. Thus, our findings that mitochondrial resident ERβ specific ligand, DPN can attenuate the mitochondrial defects caused by Aβ treatment highlight the possibility that this pathway may be a useful mitochondria-directed therapeutic target for Alzheimer's disease. Title: Dimebon/Latredipine is a potent activator of AMP-activated protein kinase (AMPK) and reduces neuronal excitability

Authors: *P. WEISOVA[1], S. PEREZ ALVAREZ[2], S. KILBRIDE[2], U. ANILKUMAR[2], B. BAUMANN[2], J. JORDÁN[3], T. BERNAS[4], H. J. HUBER[2], H. DÜSSMANN[2], J. H. M. PREHN[2]; [1]Mol. Cell Biol., Vienna Biocenter, Vienna, Austria; [2]Royal Col. of Surgeons in Ireland, Dublin, Ireland; [3]Univ. de Castilla-La Mancha, Albacete, Spain; [4]Nencki Inst. of Exptl. Biol., Warsaw, Poland

Abstract: Dimebon/Latredipine is a small molecule compound with attributed neurocognitive enhancing activities which has recently been tested in clinical trials for the treatment of Alzheimer's and Huntington's disease. Dimebon has been suggested to be a neuroprotective agent that increases mitochondrial function, however the molecular mechanisms underlying these activities have remained elusive. We here demonstrate that Dimebon, at (sub)nanomolar concentrations (0.1 nM) activates the energy sensor, AMP-activated protein kinase (AMPK). Treatment of primary neurons with Dimebon increased intracellular ATP levels and glucose transporter 3 translocation to the plasma membrane. Dimebon also increased mitochondrial uptake of the voltage-sensitive probe TMRM. Gene silencing of AMPKα or its upstream kinases, LKB1 and CaMKKβ, inhibited this effect. However, studies using the plasma membrane potential indicator $DisBAC_2(3)$ demonstrated that the effects of Dimebon on TMRM uptake were largely mediated by plasma membrane hyperpolarization, precluding a pure 'mitochondrial' mechanism of action. In line with a stabilizing effect of Dimebon on plasma membrane potential, pre-treatment with Dimebon reduced spontaneous Ca^{2+} oscillations as well as glutamate-induced Ca^{2+} increases in primary neurons, and protected neurons against glutamate toxicity. In conclusion, our experiments demonstrate that Dimebon is a potent activator of AMPK, and suggest that one of the main pharmacological activities of Dimebon is a reduction in neuronal excitability.

Title: Mild inhibition of the mitochondrial pyruvate carrier is neuroprotective and potentiates metabolic flexibility

Authors: A. S. DIVAKARUNI[1], A. Y. ANDREYEV[1], T. P. CIARALDI[3], *A. N. MURPHY[2]; [1]Pharmacol., UCSD, La Jolla, CA; [2]UCSD, LA JOLLA, CA; [3]Med., Univ. of California, San Diego, and VA San Diego Hlth. Syst., La Jolla, CA

Abstract: A growing body of data has established that not only metabolic dysfunction contributes to the development of Alzheimer's Disease (AD), but also that type 2 diabetes and AD may share an overlapping etiology. As such, many anti-diabetic pharmaceuticals, such as incretin analogs and thiazolidinediones (TZDs) are experimentally neuroprotective and are being repurposed for the treatment of AD. Previous work in our laboratory has shown that TZDs are acute, specific inhibitors of the mitochondrial pyruvate carrier [MPC, Divakaruni et al. (2013) PNAS. 110:14. 5422-7], and may have pleiotropic effects including mild inhibition of the MPC that enhances the metabolic profile in skeletal muscle myocytes. Here we show that in primary cortical neurons, mild MPC inhibition with UK5099 can stimulate glucose uptake at the plasma membrane, potentiate the oxidation of alternative substrates such as ketone bodies and amino acids, protect against glutamate-induced excitotoxic injury, and lower reactive oxygen production in isolated mitochondria. Taken together, these data demonstrate that mild inhibition of the MPC is experimentally neuroprotective. Moreover, they establish the mitochondrial pyruvate carrier as a promising therapeutic target for the treatment of AD and other neurodegenerative diseases that may be rooted in dysregulated glucose metabolism.

Title: Mitochondrial dysfunction is associated with impairments in synaptic plasticity and memory in the TgCRND8 and 3xTg mouse models of Alzheimer's disease

Authors: W. SNOW[1], S. R. CHOWDHURY[1], S. ALASHMALI[2], C. R. LIAO[3], K. OIKAWA[4], M. RAK[3], E. THOMSON[4], C. HIRSCHMUGL[5], E. PLATT[4], M. SUH[2], K. GOUGH[3], P. FERNYHOUGH[1,4], *B. C. ALBENSI[1,4];

Abstract: Objective. Mitochondrial dysfunction has been implicated as a disease component of Alzheimer's disease (AD). To address whether mitochondrial function is altered with the progression of AD and changes in memory, mitochondrial bioenergetic profiles, ATP assessment, pathological evaluation, long term potentiation (LTP), and memory were evaluated in the TgCRND8 and 3xTg mouse models of AD.
Methods. Morris water maze (MWM) experiments were conducted on control vs. Tg mice. Subsequently, hippocampal tissues from age-matched control and TgCRND8 mice at ages 2, 6, and 14 mos and 3xTg mice at age 12 mos were used as a source of mitochondria. LTP was also assessed in some hippocampal slices. The XF24 analyzer from Seahorse Bioscience was used to measure the rates of oxygen consumption in freshly isolated mitochondria. Amplex Red kits were used to detect the level of H_2O_2. FTIR spectrochemical imaging was used to identify amyloid plaque formation and composition in brain slices.
Results. 3xTg and TgCRND8 strains were found to have deficits in LTP and MWM parameters. In addition, mitochondrial bioenergetics parameters (basal respiration, coupled respiration, maximal uncoupled respiration, respiratory control ratio - coupled and uncoupled, spare respiratory capacity) were higher, but not significant, in hippocampal mitochondria from TgCRND8 mice at 2 mos compared to age-matched control littermates. The mitochondrial bioenergetics parameters were not found to be altered between control and TgCRND8 mice at 6 months. With the progression of age to 14 mos, coupled respiration, maximal respiration and spare respiratory capacity were decreased by 45-55% in TgCRND8 mice compared with control hippocampal mitochondria. In the 3xTg model at 12 mos, basal respiration, uncoupled

respiration and spare respiratory capacity were significantly diminished compared to control. However, the generation of H_2O_2 derived from cortical and hippocampal mitochondria, was significantly higher in controls compared to 3xTg mice. Plaques formed after 12 mos were surrounded and infiltrated with lipid.
Conclusion. These data suggest that altered mitochondrial function and oxidative stress are linked to the progression of AD, which are associated with deficits in synaptic plasticity and memory.

Title: Uptake of tau antibodies and paired helical filament enriched tau protein in naïve and transfected human neuroblastoma cells

Authors: *D. B. SHAMIR[1], N. ROSENQVIST[4], M. D. GREGORY[2], S. RASOOL[1], J. T. PEDERSEN[4], E. M. SIGURDSSON[3];

Abstract: Our laboratory has pioneered targeting pathological tau proteins for clearance with active and passive immunotherapies. We have shown that this approach leads to antibody uptake into neurons, clears tau aggregates from the brain and prevents functional impairments, such as cognitive decline, in mouse tauopathy models.
Antibody-mediated clearance of tau likely involves intra- and extracellular pathways. To clarify

the mechanism of action of tau antibodies, we are using several in vitro models, including naïve and transfected (0N4R P301L tau) SHSY5Y human neuroblastoma cells. To accurately quantitate antibody uptake under various conditions, we have developed a flow cytometry protocol. With this novel approach, saturation of cellular uptake of a tagged antibody (targeting the non-phosphorylated Ser396/404 tau epitope) was observed at 40-50 μg/ml after 24 h incubation. Naïve and transfected cells had similar dose uptake curves with this antibody under normal conditions. By microscopy, the tau antibody was primarily located in the endosomal-lysosomal (E-L) system as detected by co-staining with such markers. Live cell imaging with phase and confocal microscopy allowed much greater detection of internalized antibodies than the fixed confocal procedure, suggesting that the latter (fixation with several washes) leads to an under estimation of cellular antibody uptake.
To better mimic a pathological state, the cells were incubated with paired helical filament (PHF) enriched Alzheimer's Disease (AD) brain protein preparation. Uptake of tagged PHF saturated at 1 μg/ml as assessed by flow cytometry, and it was primarily found in the E-L system as detected by microscopy. Pre-incubation of the cells with PHF (0.1-10 μg/ml) for 24 h, did not affect subsequent tau antibody uptake after 24 h in either cell line. However, co-incubation with PHF (0-10 μg/ml) for 24 h dose-dependently decreased tau antibody uptake to a similar extent in naïve and transfected cells, up to 41±0.1% and 33±0.2%, respectively. This was expected as the formation of extracellular antibody-PHF complexes is likely to lead to decreased cellular antibody uptake. Under both conditions, the tau antibody and PHF co-localized within the cells as revealed by microscopy. We are currently studying the uptake mechanisms in further detail to clarify intracellular clearance mechanisms. Overall, a better understanding of underlying cellular mechanisms for tau immunotherapy and the use of our flow cytometry protocol will facilitate development of this promising approach to treat AD and related tauopathies.

Title: Mitochondria-targeted plastoquinone antioxidant SkQ1 prevents amyloid-β-induced impairment of long-term potentiation in rat hippocampal slices

Authors: *V. G. SKREBITSKY[1], N. A. KAPAY[1], O. V. POPOVA[1], E. V. STELMASHOOK[1], R. V. KONDRATENKO[1], N. K. ISAEV[2], D. B. ZOROV[2], V. P. SKULACHEV[2];
[1]Res. Ctr. of Neurology, Russian Acad. of Med. Sciens, Moscow, Russian Federation;
[2]Lomonosov Moscow State University, Belozersky Inst. of Physico-Chemical Biol., Moscow, Russian Federation

Abstract: Bath application of 200 nM amyloid-β 1-42 (Aβ) to rat hippocampal slices impairs induction of long-term potentiation (LTP) of the population spike (PS) in pyramidal layer of the CA1 field of the hippocampus. Intraperitoneal injection of mitochondria-targeted plastoquinone derivative SkQ1at very low concentrations (250 nmol/kg body weight) given 24 h before the slice preparation or 1 h treatment of hippocampal slices with 250 nM SkQ1 prevents the deleterious effect of Aβ on LTP. To elucidate which part of the molecule is responsible for this type of neuroprotective activity, the effect of the analog of SkQ1 lacking plastoquinone (C12TPP) was studied. It was found that C12TPP was much less efficient in LTP protection than SkQ1 itself. It means that plastoquinone part of SkQ1 molecule is responsible for the LTP rescue. To summarize, in vivo and in vitro injection of SkQ1 compensates for Aβ-induced oxidative damage of long-term synaptic plasticity in the hippocampus, which is considered to be the main reason of memory loss and impairment of other cognitive functions associated with Alzheimer's disease (AD). Therefore, SkQ1 may be considered as a promising candidate for the treatment of early-stage of AD.

Title: The effect of SIRT1 on the protein degradation in cholinergic neuron

Authors: *T. KIM, H. SEO;
Dept. of Mol. and Life Sci., Hayang Univ., Ansan, Gyeonggi, Korea, Republic of

Abstract: SIRT1 is a prominent member of family of NAD^+ dependent class III histone deacetylase (HDAC) and has been emphasized the importance in the regulation of metabolism, energy homeostasis, stress tolerance, cellular survival, and organismal lifespan. In this study, we have examined the cellular effects of overexpression of SIRT1 in cholinergic neuron. SIRT1 overexpression reduced the mRNA expression of mitochondrial fission gene, dynamin-related protein 1 (Drp1) and altered the level of related calcium signaling. The overexpression of SIRT1 changed the chymotrypsin activities in ubiquitin proteasome system (UPS) and the level of microtubule-associated protein 1A/1B-light chain 3 (LC3) in autophagy. The treatment of MG132, reversible proteasome inhibitor, decreased the endogenous level of SIRT1 in cholinergic neuron. We also used various inhibitors to find the function of endogenous SIRT1 in cellular protein degradation system. These results suggest that the function of SIRT1 is closely related to the regulation of mitochondrial cycle and cellular protein degradation system in cholinergic neuron.

Title: Combination of ketamine and AMPA promotes survival of cells expressing amyloid-beta and presenilin: Implication for Alzheimer’s disease

Authors: *L. AKINFIRESOYE[1], K. F. MANAYE[2], Y. TIZABI[1];
[1]Pharmacol., [2]Physiol. and Biophysics, Howard Univ. Col. of Med., Washington, DC

Abstract: Alzheimer's disease (AD) is a progressive age-related neurodegenerative disease characterized by cognitive impairments and formation of plaques and tangles. Cellular models whereby expression of beta amyloid (Aβ), the major component of plaques, is exaggerated are commonly used to test the efficacy of novel neuroprotective compounds. In addition to Aβ, mutation in the protein presenilin has also been shown to contribute to Alzheimer's pathology. Recently, a cellular neuroblastoma model where both beta amyloid and mutated presenilin are expressed has become available. Since in-vitro protective effects of ketamine and AMPAkines against several neuronal toxins have been observed, we hypothesized that ketamine and/or AMPA will also protect against cellular damage or death due to high expression of Aβ or Aβ and presenilin. Wild type neuroblastoma (N2a) cell line and those transfected with APP_{695} (singly transfected) or the combination of APP_{695} and presenilin (doubly transfected), were pretreated with various concentrations of ketamine (0.01 - 1.0 mM), AMPA (1- 100 nM) or their combination (ketamine 0.1 mM and AMPA 100 nM) and the survivability of the cells was determined by MTT Assay after 72 hours. Pretreatment with neither ketamine nor AMPA provided any protection against cellular loss in all cell lines. However, the combination of ketamine and AMPA had a protective effect that was more pronounced in the doubly transfected cell line. These results suggest novel glutamatergic-based intervention (i.e., combination of an NMDA antagonist with an AMPA agonist) in AD.

Title: The effects of selective histone deacetylase inhibitors in cholinergic neurons

Authors: *H. NOH, H. SEO*;
Dept. of Mol. and Life Sci., Hanyang Univ., Ansan, Gyeonggi, Korea, Republic of

Abstract: Some of histone deacetylase (HDAC) inhibitors are recently reported as neuroprotectors by improving synaptic plasticity, learning and memory in diverse neurodegenerative disorders. We previously studied that valproic acid (VPA), non-specific HDAC inhibitor (HDACI) increased nerve growth
factor (NGF) expression and improved an impaired memory in Alzheimer's disease model mice (Noh and Seo, 2012). To determine the effects of selective HDACI *in vitro*, various inhibitors such as apicidin, VPA, suramin, sodium butyrate, MS-275, AGK-2, nicotinamide, tubacin, etc. were administered in cholinergic neurons in culture. We detected the altered mRNA levels of trophic factors and related trophic factor receptors after HDACI treatment. We also detected the increased levels of several nuclear receptors after HDACI treatment. These data suggest that histone acetylation plays key roles in the expression and function of trophic factors in cholinergic neurons.

Title: Hybrids of AChE inhibitor and memantine derivatives as candidates for Alzheimer´s disease treatment

Authors: *O. SOUKUP[1,4], J. KORABECNY[2,4], K. MUSILEK[2,5], D. JUN[3], J. ZDAROVA KARASOVA[1], J. MISIK[2], K. KUCA[3,4];
[1]Publ. Hlth., [2]Toxicology, [3]Ctr. for Advanced Studies, Univ. of Defence, Hradec Kralove, Czech Republic; [4]Biomed. Res. Ctr., Univ. Hosp. Hradec Kralove, Hradec Kralove, Czech Republic; [5]Chem., Univ. of Hradec Kralove, Hradec Kralove, Czech Republic

Abstract: Current treatment of for Alzheimer´s disease (AD) consists of acetylcholinesterase inhibitors (AChEi) and memantine, which is an amantadine derivative capable of antagonizing

excitotoxicity mediated by NMDA receptors. The first introduced AChEi was tacrine, however, due to its severe side-effects (hepatotoxicity and cholinergic effects upon the gastrointestinal tract) resulted in its withdrawn from the market. On the other hand, recent development of tacrine related agents revealed that 7-methoxytacrine (7-MEOTA) as less toxic derivative with similar pharmacological profile. In the search for new drug candidates, we synthesized and biologically assessed (Ellman´s method) new 7-MEOTA and amantadine hybrids combining two different approaches, AChEi and NMDA antagonist, in a single molecule. The biological in vitro evaluation revealed that some of these molecules were good inhibitors of AChE, sometimes overcoming the efficacy of tacrine. Structure-activity study revealed that affinity towards AChE was independent on whether urea or thiourea linker was used and the best activity exerted compounds with 5 carbon linker between both pharmacophores. The most promising were also evaluated for their toxicological effects anf for pharmacokinetic properties. We believem, that some of them could be qualified as potential novel anti-AD drug candidate if antiNMDA efficacy will be confirmed as well.

Title: Mild impairment of the citric acid cycle in neurodegenerative diseases promotes mitophagy/autophagy

Authors: *K. BANERJEE[1], T. DENTON[2], G. E. GIBSON[1];
[1]Neurosci., Weill-Cornell Med. Col. at Burke Med. Res. Inst., White Plains, NY; [2]Eastern Washington Univ., Cheney, WA

Abstract: Introduction: Decreased mitochondrial function, as reflected by reduced brain glucose utilization, is an invariant feature of Alzheimer’s disease (AD). Indeed, diminished mitochondrial function is a common feature of many age-related neurodegenerative diseases. The alpha-ketoglutarate dehydrogenase complex (KGDHC), a key enzyme complex in mitochondrial energy production, is diminished in AD and many other age-related neurodegenerative disorders. If diminished mitochondrial function is either an initiating event or

a critical step in a cascade of events, then the mitochondrial deficit should be linked to the abnormal accumulation of protein aggregates as well as to oxidative and mitophagic/autophagic stress, which are hallmarks of these disorders.
Objective: The goal of this study was to determine if inhibiting just one key mitochondrial enzyme, KGDHC, would initiate these processes.
Methods: Migration of cytosolic proteasomal proteins to the mitochondria initiates mitophagy (mitochondrial breakdown). Mitochondria and cytosol from SHSY5Y cells (control and treated) were isolated by differential centrifugation. Immunoblotting with antibodies to parkin and microtubule-associated protein light chain 3 (LC3) were performed to detect migration of several proteins from cytosol to different subcellular fractions. An increased LC3II/LC3I ratio in the mitochondrial fraction is an indicator of mitophagy. Confocal imaging was performed to confirm autophagy using green "autophagy detecting dye" that binds with autophagosomes. Cell-death was measured by trypan blue exclusion method and tetramethylrhodamine (TMRM) was used for detecting mitochondrial membrane potential.
Result: Carboxyethyl succinyl phosphonate (CESP) is a specific inhibitor of KGDHC that has been shown to penetrate into cells. CESP (100 µM, 5 h) diminished the mitochondrial membrane potential by about 40%. Under these conditions, cytosolic parkin declined by 25% while mitochondrial parkin increased by 20%. The LC3II/LC3I ratio increased in the mitochondrial fraction suggesting CESP induced mitophagy. Confocal imaging using the “autophagy detecting dye” confirmed the presence of autophagy in mitochondrial fraction after CESP treatment. This dye showed that other areas of the cell were also involved in autophagy. CESP treatment increased cell death by about 15%.
Conclusion & Significance: The results suggest that proteasomal activators and/or activation of KGDHC may protect against toxicity due to altered protein translocation. An understanding of the link between mitochondria and proteasomal activity may promote the development of new therapeutic strategies.

Title: Rexinoids enhance LXR target gene expression in primary microglia and astrocytes

Authors: *M. LAKNER[1], C. E. WAGNER[2], P. E. CRAMER[1], G. E. LANDRETH[1];
[1]Neurosci., Case Western Reserve Univ., Cleveland, OH; [2]Sch. of Mathematical and Natural Sci., Arizona State Univ., Glendale, AZ

Abstract: Alzheimer's disease (AD) is characterized by the accumulation of amyloid beta within the brain and progressive neurodegeneration resulting from imbalance in production and clearance of soluble Aβ (sAβ) peptides. The clearance of sAβ from the brain is reliant upon apolipoprotein E (ApoE) and its lipidation status. Elevation of the lipidated forms of ApoE is associated with reduced sAβ levels, plaque burden and enhanced cognition. The expression of ApoE and its lipid transport genes ATP binding cassette A1 (ABCA1), and ABCG1 are coordinately regulated by the nuclear receptors, retinoid-X-receptor (RXR): liver-X-receptor (LXR) and RXR: peroxisome proliferator activated receptor γ (PPARγ). Recently, Cramer et al (2012) showed that treatment with the FDA approved RXR agonist Bexarotene rapidly cleared amyloid and improved cognition in murine models of the disease. We have tested RXR agonists (rexinoids) in primary glia cell cultures for their ability to induce the expression of ApoE/ABCA1/ABCG1 and to proteolytically degrade Aβ. We show that treatment of primary microglia and astrocytes with synthetic RXR agonists increases the proteolytic degradation of sAβ and this effect correlates with expression of ABCA1 and ApoE. These data confirm the hypothesis that agonism of RXRs can sufficiently promote the clearance of soluble amyloid beta and provide insight into the efficacy of the Bexarotene pharmacophore.

Title: Cyclopamine modulates APP metabolism and decreases Aβ generation

Authors: *A. G. VOROBYEVA, S. MILLER, R. LEE, P. KHANDELWAL, G. DISTEFANO, A. GANGEMI, D. MARENDA, A. SAUNDERS;
Biol., Drexel Univ., Philadelphia, PA

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disease leading to memory loss. Particularly important is the synaptic loss observed in the hippocampus, the center of learning and memory. Numerous lines of evidence suggest that Aβ, a neurotoxic peptide, initiates a cascade that ultimately results in synaptic dysfunction and eventually neuronal death. Aβ is generated from Amyloid Precursor Protein (APP) by the proteolytic process of β- and γ-secretases and alterations to this processing can result in AD. Using an *in vitro* model we observed an increase in APP-CTFs and a decrease in Aβ and AICD upon cyclopamine treatment. We observed similar effects of cyclopamine on APP metabolism using a transgeneic Drosophila AD model. These results suggest cyclopamine inhibits γ-secretase and leads to decreased APP proteolytic cleavage and Aβ generation. Taken together, our data strongly suggests cyclopamine is a novel regulator of APP metabolism and may rescue the effects of neurotoxic peptide Aβ observed in other AD models.

Title: Diet-enriched in palmitate triggers Alzheimer's like pathology

Authors: *O. GHRIBI, S. RAZA;
Pharmacol, Physiol & Therapeut., UND Med. Sch., GRAND FORKS, ND

Abstract: Several studies suggest that dietary regimens rich in fat and carbohydrates can increase the risk for atherosclerosis, type 2-diabetes, and metabolic syndrome, and may thus increase the risk for Alzheimer’s disease (AD). It is particularly relevant that dietary supplements containing key nutrients may improve cognitive functioning in demented patients. Thus, depending on their components, diets can promote AD or can represent a therapeutic avenue for this disease. It is therefore important to continue exploring the potential triggering or protective roles of diets in the pathogenesis of AD. In the present studies, we demonstrate that the saturated free fatty acid (sFFA) palmitate can trigger AD-like pathology in human neuroblastoma cells as well as wild type mice and accelerates AD-like pathology in the 3xTg-AD mice. Incubation of human neuroblastoma cells with palmitate increased levels of BACE1 levels, soluble Aβ, NF-

κB, and the endoplasmic reticulum stress marker gadd153 (also called CHOP). Inhibiting gadd153 with siRNA or with compounds that inhibit gadd153 activation precluded palmitate-induced increase in BACE1, NF-κB and Aβ. On the other hand, palmitate feeding for 3 months induces gadd153 and NF-κB activation, increases BACE1 and Aβ42 levels, and activates astrocytes and microglia in wild type mice. Furthermore, feeding a diet rich in palmitate accelerated AD-like pathology in the 3xTg-AD compared to 3xTg-AD fed a normal diet. While 3 month-old 3xTg-AD fed a normal diet for 3 months showed increased APP expression levels only, age-matched 3xTg-AD fed a diet rich in palmitate for 3 months showed increased soluble Aβ levels, increased ER stress and gadd153 activation, and synaptic loss. Altogether, our results demonstrate that palmitate can generate pathological hallmarks in vitro and in vivo relevant to AD pathology. We further suggest that ER stress-mediated gadd153 activation plays an important role in palmitate effects. Diets rich in palmitate may increase the risk for AD in humans and inhibition of gadd153 may protect against palmitate-induced AD-like pathology.

Title: Elevated lysosomal pH and autophagy dysfunction in human fibroblasts bearing the Alzheimer's-associated presenilin 1 A246E mutation can be ameliorated with cAMP

Authors: *E. E. COFFEY[1], J. M. BECKEL[1], A. M. LATIES[2], C. H. MITCHELL[1];
[1]Anat. and Cell Biol., [2]Ophthalmology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Alzheimer’s disease is one of a number of neurodegenerative disorders characterized by the pathological accumulation of protein, both intracellularly and extracellularly. A

particularly robust autophagic phenotype is also observed in Alzheimer's disease, a pathology that includes the build-up of partially degraded protein and cellular material in enlarged lysosomes and autophagosomes. This phenomenon is reportedly accentuated by certain mutations in the presenilin 1 (PS1) subunit of gamma-secretase. It had previously been suggested that PS1 mutation exerts this effect by perturbing lysosomal pH, leading to an overall degradative inefficiency; however, subsequent studies were unable to validate this effect. The current study aimed to further assess this reported acidification deficit and some of its cellular consequences. In human skin fibroblasts containing the A246E mutation in PS1, a slight elevation of lysosomal pH, on the order a fifth to a third of a pH unit, was indeed detected. This pH elevation was accompanied by increased levels of autophagosomal markers, such as an increased ratio of LC3B-II/-I and of p62, indicating an accumulation of autophagosomes within PS1 fibroblasts, and supporting the idea that PS1-linked pH elevation results in a backlog of intracellular degradation. Further investigation by qPCR revealed increased expression of the following genes in PS1 mutated fibroblasts as compared to wild-type fibroblasts: ATP6V1B2, a subunit of the proton pump responsible for lysosomal acidification; ATG5, associated with autophagosomal membrane elongation; BECN1, involved in autophagosome genesis; and TcfEB, a transcription factor that both links lysosomal and autophagic processes and also contributes to lysosomal acidification. These findings indicate that PS1 fibroblasts also exhibit a general disruption of the lysosomal-autophagosomal axis and could indicate a compensatory response to chronic pH elevation. Finally, the current study also identified that increased levels of intracellular cAMP - previously shown to restore acidic pH to pathologically or pharmacologically disrupted lysosomes - are also able to restore pH in PS1 fibroblasts, and that this pH restoration is mirrored by a reduction in LC3B-II/-I ratio, indicating that pH restoration also improved clearance of material through the degradative system. Overall, these data suggest that the PS1 mutation not only contributes to autophagic pathology in Alzheimer's disease through elevated lysosomal pH, but that this pathology can be ameliorated by lysosomal re-acidification - perhaps indicating an untapped line of future therapeutic potential.

Title: γ-Secretase inhibitor LY450139 does not impair cognitive function in wild type mice

Authors: *N. DEVIDZE[1], S. SANKARANARAYANAN[1], B. SNYDER[1], D. BRYCE[1], A. LIN[1], C. POLSON[1], S. KEENAN[1], R. OLSON[2], J. TOYN[1], C. CONWAY[1], C. F. ALBRIGHT[1], J. MEREDITH[1], M. AHLIJANIAN[1];

Abstract: One of the major hallmarks of Alzheimer's disease (AD) is the accumulation of senile plaques composed of Amyloid-β (Aβ) deposits. The sequential cleavage of Amyloid precursor protein (APP) by β-secretase (resulting in a carboxy-terminal fragment of APP, β-CTF) and the γ-secretase enzyme complex, results in the generation of multiple Aβ peptides. Trials of γ-secretase inhibitors (GSI) in AD subjects achieved limited effects on Aβ levels, and did not improve cognitive function. In order to explore the impact of GSI on cognition, we investigated the effect of acute, or sub chronic administration of LY450139 (semagacestat) in female and male wild type (WT) mice on cognitive endpoints and brain Aβ and β-CTF levels. Mice were tested in 2 behavioral paradigms; the Y-Maze spontaneous alternation test (working memory) and the Two-Trial Y-maze test (spatial learning and memory). Mice were administered LY450139 (60 to 100 mg/kg) or vehicle PO for 1 or 8 days with behavioral testing occurring 3 hours after the final dose. Immediately after behavioral testing, brains and plasma were collected for biochemical analysis and to determine drug exposure. LY450139 treatment led to a dose dependent reduction in brain Aβ40 and Aβ42 and a corresponding increase in β-CTF. There were no changes in the cognitive measures at any dose of semagacestat, including those doses that inhibited Aβ40 and 42 and increased β-CTF. These results contrast with previous reports of cognitive decrements in WT mice given LY450139, and highlight the need for further investigation to understand the effects of γ-secretase inhibition on cognitive function.

Title: Investigating the effects of β-secretase inhibitor, GRL-8234, on age-dependent synaptic deficits in APPswe;PS1deltaE9 mice

Authors: *A. L. MEGILL[1], P. C. WONG[2], A. KIRKWOOD[1], H.-S. HOE[3], H.-K. LEE[1]; [2]Pathology, [1]Johns Hopkins Univ., Baltimore, MD; [3]Neurosci., Georgetown Univ., Washington, DC

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disorder, causing loss of synaptic contacts and cognitive decline. Current theories implicate the production of amyloid beta (Aβ) as a key molecular event that ultimately leads to neuronal degeneration and the clinical pathology seen in AD (Hardy and Selkoe, 2002). Aβ is produced by sequential proteolytic cleavage of amyloid precursor protein (APP) by two endoproteolytic enzymes, β- and γ-secretase. Therefore, inhibiting the activity of these enzymes has surfaced as one of the major disease-modifying approaches for AD (Citron, 2004).
Equally important in developing effective therapies for disease intervention is to understand how Aβ production alters normal synaptic function and what types of synaptic functions are differentially affected by Aβ (Wang and Megill et al., 2012). Increasing evidence suggests the cognitive syndromes found in AD patients are preceded by changes in synaptic efficacy (Shankar and Walsh, 2009; Selkoe, 2002). Therefore, examining whether different strategies that target APP-processing enzymes rescue synaptic dysfunctions associated with AD is important. We found that at the Schaffer collateral inputs to CA1, APPswe;PS1deltaE9 mice show age-dependent alterations in synaptic plasticity. In particular, long-term potentiation (LTP) induced with a four-train theta burst (4xTBS) protocol was decrease in adult (6 month old) mice while long-tem depression (LTD) induced with a paired pulse 1Hz (pp-1Hz) protocol was increased. In order to try and rescue these synaptic deficits, APPswe;PS1deltaE9 mice were treated with the β-secretase inhibitor, GRL-8234. GRL-8234 has been show to rescue age related cognitive decline and decrease Aβ production in Tg2576 mice (Chang et al., 2011). While GRL-8234 was able to decrease Aβ production in the hippocampus of APPswe;PS1deltaE9 mice, it did not significantly improve LTP expression. Furthermore, GRL-8234 reduced LTP expression in wildtype mice, comparable to levels seen in APPswe;PS1deltaE9 mice. On the other hand, GRL-8234 did not negatively affect LTD in wildtype mice and we are currently testing its effects on LTD in APPswe;PS1deltaE9 mice.

Title: Palmitate induces transcriptional regulation of BACE1 and presenilin by STAT3 in neurons mediated by astrocytes

Authors: *L. LIU, R. MARTIN, C. CHAN;
Michigan State Univ., East Lansing, MI

Abstract: Deregulation of calcium has been implicated in neurodegenerative diseases, including Alzheimer's disease (AD). Previously, we showed that saturated free-fatty acid, palmitate, causes AD-like changes in primary cortical neurons mediated by astrocytes. However, the molecular mechanisms by which conditioned media from astrocytes cultured in palmitate induces AD-like changes in neurons are unknown. This study demonstrates that this condition media from astrocytes elevates calcium level in the neurons, which subsequently increases calpain activity, a calcium-dependent protease, leading to enhance p25/Cdk5 activity and phosphorylation and activation of the STAT3 (signal transducer and activator of transcription) transcription factor. Inhibiting calpain or Cdk5 significantly reduces the upregulation in nuclear level of pSTAT3, which we found to transcriptionally regulate both BACE1 and presenilin-1, the latter is a catalytic subunit of γ-secretase. Decreasing pSTAT3 levels reduced the mRNA levels of both BACE1 and presenilin-1 to near control levels. These data demonstrate a signal pathway leading to the activation of STAT3, and the generation of the amyloid peptide. Thus, our results suggest that STAT3 is an important potential therapeutic target of AD pathogenesis.

Title: Blockage of the cholesterol biosynthesis reduces γ -secretase activity and Aβ generation

Authors: *Y. KIM;
Dept. of Biomed. Sci., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Amyloid beta (Aβ) is one of major causative molecules for Alzheimer's disease (AD) pathogenesis. It is derived from amyloid precursor protein (APP) by sequential cleavages of β- and γ-secretases. The regulation of these components has been postulated to be an important factor for Aβ generation in the pathogenesis of AD. Molecules in γ-secretase complex and APP are present in lipid raft where cholesterol regulates integrity and flexibility of membrane protein. However, the relation between cholesterol contents and Aβ generation has been controversial. In this study, we used the AY9944 to inhibit cholesterol biosynthesis at the last step of cholesterol biosynthesis, which decreases the side effect like statin. Treatment of AY-9944 decreases the γ-secretase activity and Aβ generation by the disruption of lipid raft, in which APP and γ-secretase complex including nicastrin are colocalized. The effect of AY-9944 is measured by live cell imaging using novel FRET assay system. It suggests that the cholesterol is an important factor to modulate APP processing and Aβ generation.

Title: BACE 1 contributes to impaired neural network function and neuritic dystrophy in cortical neurons generated from patients with Alzheimer's disease

Authors: *V. DANG, J. BRIGHT, S. HUSSAIN, L. NGUYEN, E. BEATTI, Z. YANG, S. WRIGHT, U. SHOUKAT-MUNTAZ, J. DIMOS, S. OIRION, P. CONLEY, N. STAGLIONO, I. GRISWALD-PRENNER;
Ipierian Inc., South San Francisco, CA

Abstract: Altered neuronal network activity and degeneration of neuronal processes have been linked to memory loss and impaired cognitive function associated with Alzheimer's disease (AD). To understand how these processes develop and progress, cortical neurons (CNs) were differentiated from induced pluripotent stem cells (iPSCs) derived from healthy and AD patients (familial and sporadic). Using synaptically driven bursts of action potentials as a measure of

neural network activity, we report that AD patient-derived CNs have reduced bursting activity over time ($p < 0.03$; one-tail paired t-test), whereas parallel cultures of healthy patient-derived CNs show increased bursting activity over time ($p < 0.001$; one-tail paired t-test). Concurrent with the reduction of bursting activity, CNs that failed to burst also have dystrophic neurites and reduced miniature excitatory post-synaptic current frequency. Treatment with a BACE 1 inhibitor reduced the levels of A-Beta in the culture media and prevented the decrease in bursting activity and neuritic dystrophy in familial and sporadic AD patient-derived CNs. These results suggest that BACE 1 contributes to impaired network activity and neuritic dystrophy in AD patient-derived CNs and that iPSC-derived CNs are a relevant disease model for the study of mechanisms of neuronal network dysfunction in AD.

Ctr/Nathan Kline Inst., ORANGEBURG, NY

Abstract: We previously reported that presenilin-1 (PS1) deletion in mouse blastocysts, neurons, and PS1 mutation in Alzheimer's patient fibroblasts selectively inhibits lysosomal proteolysis and autophagy by blocking lysosomal acidification (Lee et al. Cell, 2010). Here we demonstrate that the V0a1 subunit of vATPase is essential for lysosomal acidification and that its maturation, lysosomal delivery, and function are strikingly deficient in neurons and MEFs from mice lacking PS1. In highly purified lysosomes of PS1KO cells, levels of V0a1 subunit are less than 20% of wild-type (WT) levels and lysosomal proton translocation activity is reduced by approximately 50%. siRNA knockdown of either V0a1 subunit or PS1 in WT neuronal cells reproduces the complete phenotype of lysosomal abnormalities and autophagy failure seen in PS1 KO cells. Elevated lysosomal pH in PS1-deficient cells causes abnormal efflux of calcium from lysosomes and a rise in cytosolic calcium levels. Restoring lysosomal calcium to normal levels in PS1KO cells neither re-acidifies lysosomes nor reverses lysosomal proteolytic and autophagic deficits. By contrast, re-acidification of lysosomes of PS1-deficient cells using acidic nanoparticles targeted to lysosomes reverses autophagy failure and restores normal lysosomal proteolysis and calcium homeostasis. Moreover, elevating lysosomal pH by blocking vATPase activity with concanamycin A induces lysosomal calcium efflux in WT cells but does not worsen the

abnormal calcium efflux in PS1KO cells, which is already enhanced by vATPase deficiency. Collectively, our studies show that v-ATPase deficiency is the principal basis for autophagy deficits in PS-FAD and is a major contributor to abnormal calcium homeostasis - a second well-established γ-secretase independent deficit resulting from PS1 loss of function. Restoration of lysosomal function and autophagy in PS1-deficient cells by re-acidifying lysosomes suggests novel approaches to therapy for AD and possibly other neurodegenerative conditions. Supported by the National Institute on Aging.

Title: CALM impacts on Aβ42 production ratio through modulation of clathrin-mediated endocytosis of γ-secretase

Authors: *K. KANATSU[1], Y. MOROHASHI[1], T. WATANABE[2], T. TOMITA[1], T. IWATSUBO[1,3];
[1]Dept Neuropathol & Neurosci, Univ. Tokyo Grad Sch. Pharmaceu Sci., Tokyo, Japan; [2]Dept Biol Sci, Nara Women's Univ. Grad Sch. Hum & Sci., Nara, Japan; [3]Dept Neuropathol, Univ. Tokyo Grad Sch. Med., Tokyo, Japan

Abstract: Alzheimer disease (AD) is the most common type of dementia worldwide. Several lines of evidence suggest that aberrant production, clearance and aggregation of amyloid-β peptide (Aβ) in brain are linked to the etiology of AD. Recently, genome-wide association studies (GWASs) in late-onset AD patients have reported evidence that variation in phosphatidylinositol binding clathrin assembly protein (PICALM) gene confers a genetic risk for AD. A following meta-analysis using GWAS data has revealed that these variants in PICALM showed strong genetic interaction with another risk gene APOE ε4, suggesting that PICALM could be involved in Aβ metabolism in brains. PICALM gene encodes a protein which has a PtdIns(4,5)P2-binding AP180 N-Terminal Homology (ANTH) domain at its N terminus, along with several AP2/clathrin binding motifs in the C-terminal region, indicating that CALM functions in the initial step of clathrin-mediated endocytosis through the proper formation of

clathrin coated pits on the cell surface. To investigate the role of CALM in Aβ generation, we analyzed the effects of depletion of CALM on the processing of amyloid precursor protein (APP). Intriguingly, the ratio of Aβ42, the most aggregable Aβ species, was decreased in CALM-depleted culture cells as well as in brains of Picalm+/- mice compared to those in wild-type mice. In addition, we found that γ-secretase is constitutively endocytosed via clathrin-mediated pathway, and the endocytosis of γ-secretase was significantly blocked in CALM-depleted cells. We also showed that recombinant CALM ANTH domain binds nicastrin, which is an essential component for γ-secretase. In summary, these data suggest that alteration in the rate of clathrin-mediated endocytosis by the loss of CALM affects the steady-state localization of γ-secretase, which consequently impacts on the production of pathogenic Aβ42.

Title: Generation of a faithful model for familial Alzheimer’s disease with presenilin-1 mutations

Authors: V. KURTH[1], I. OGOREK[1], T. JUMPERTZ[1], C. U. PIETRZIK[2], J. LOPEZ-RIOS[3], *S. WEGGEN[1];
[1]Dept. of Neuropathology, Heinrich-Heine-University, Duesseldorf, Germany; [2]Dept. of Pathobiochemistry, Univ. Med. Ctr. of the Johannes-Gutenberg-University, Mainz, Germany; [3]Dept. of Biomedicine, Univ. of Basel, Basel, Switzerland

Abstract: Background: The vast majority of familial Alzheimer’s disease (FAD) cases with autosomal-dominant inheritance harbor heterozygous mutations in the presenilin-1 (PSEN1) gene. PSEN1 mutations increase the proportion of the aggregation-prone Abeta42 peptide species. In addition, PSEN1 mutations have been proposed to impair crucial cellular processes including signal transduction and calcium homeostasis. However, these effects and their potential contribution to the clinical phenotype of FAD remain controversial, likely due to the

use of overexpression models that did not accurately reflect the genetic background and the biochemical composition of the gamma-secretase complex in FAD patients.
Objectives: To incorporate specific mutations into the endogenous PSEN1 gene in mouse embryonic stem (ES) cells by an innovative gene-targeting strategy termed dual recombinase-mediated cassette exchange (dRMCE).
Methods: dRMCE takes advantage of pre-targeted mouse alleles such as those generated by the International Knockout Mouse Consortium (IKMC). In these conditional alleles, the target sites for Cre and Flp recombinases can be exploited to re-engineer the genomic locus with high frequency.
Results: To introduce mutations into the conditional PSEN1 allele, we have generated replacement constructs encompassing exons 5-12 corresponding to 75% of the mouse PSEN1 protein flanked by FRT and loxP recombination sites. These constructs were co-transfected with a vector encoding both Flpo and iCre into ES cells containing the PSEN1 conditional allele. For constructs encoding either wild type or mutant PSEN1, extensive validation by PCR demonstrated successful replacement of the conditional allele with a frequency of approximately 30%. To verify equal expression of both the re-engineered PSEN1 allele and the second unmodified allele, we compared the levels of PSEN1 protein in cell clones that had undergone successful recombination with negative cell clones that contained only one functional PSEN1 allele. Densitometry analysis demonstrated that the PSEN1 expression was twice as high in positive as compared to negative cell clones, indicating that the replaced locus was fully functional and expressed normal levels of a correctly spliced PSEN1 mRNA.
Conclusions: The lack of consensus concerning the effects of PSEN mutations indicates the need for improved cellular models that account for the heterozygous expression of PSEN mutants. Our approach based on ES cells and genome editing is a cost-effective alternative to primary or iPS cells, and provides an FAD model suitable for stringently controlled biochemical and kinetic experiments.

Title: GGA3 deletion accelerates bace1 elevation and anxiety-like phenotype in 5XFAD mice

Authors: *W. KIM, K. R. WALKER, E. L. KANG, J. DONG, P. HAYDON, G. TESCO; Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: Amyloid plaques are one of the neuropathological hallmarks of Alzheimer's disease (AD) and are mainly composed of the amyloid beta peptide (Aβ), which is derived by sequential proteolytic cleavage of amyloid precursor protein (APP). Beta-Site amyloid precursor protein cleaving enzyme 1 (BACE1) initiates the generation of Aβ and is upregulated in AD brains. We have previously shown that the trafficking molecule, GGA3, plays a key role in the degradation of BACE1 regulating its trafficking to the lysosomes. More importantly we have found that levels of BACE1 in AD brains are increased and inversely correlated with GGA3 levels. Next, we have demonstrated the role of GGA3 in the regulation of BACE1 *in vivo* by showing that BACE1 levels are increased in the brain of GGA3 null mice on a congenic background. In this study, we crossed GGA3 knockout mice with a mouse model of amyloid deposition expressing five familial AD (FAD) mutations.(5XFAD mice) to determine the effects of GGA3 deletion on BACE1 levels, Aβ accumulation and behavioral deficits. Previous studies have shown that BACE1 levels are significantly increased in the cortex of 6 month-old 5xFAD mice compared to non-transgenic mice. Given that GGA3 deletion elevated BACE1 protein levels *in vivo* GGA3-/-5XFAD bigenic mice would be expected to show a significant increase in BACE1 levels before reaching the age of 6 months. Therefore, we analyzed BACE1 levels in the hippocampus and cortex of 4-month-old GGA3+/+5XFAD, GGA3+/-5XFAD and GGA3-/-5XFAD mice.
As expected, we found that BACE1 levels were increased in the hippocampus and cortex of 4 month-old GGA3-/-5XFAD mice when compared with GGA3+/+5XFAD mice or non-transgenic mice. Next, the behavioral phenotype of GGA3+/+, GGA3+/-, GGA3-/-, GGA3+/+5XFAD, GGA3+/-5XFAD and GGA3-/-5XFAD mice was assessed using a battery of tests including open field, elevated plus maze, Y-maze and contextual fear conditioning both at 4 and 7 months of age. While we did not find a significant difference among all groups in 4 month old mice, 7 month-old GGA3-/-5XFAD bigenic mice showed reduced anxiety-like behavior in the elevated plus maze compared to GGA3+/+5XFAD, GGA3-/- or GGA3+/+ mice. In conclusion, our data indicate that GGA3 deletion accelerates BACE1 elevation and anxiety-like phenotype in 5XFAD mice. We are currently investigating whether elevated BACE1 levels lead to increased Aβ deposition in GGA3-/-5XFAD mice both at 4 and 7 months of age.

Title: Pyroglutamate abeta are actively produced by cathepsin B beta-secretase in a transgenic Alzheimer's disease mouse model and neuronal-like chromaffin cells

Authors: *G. R. HOOK[1], J. YU[2,3], M. KINDY[2,3,4], V. HOOK[5];
[1]ALSP, Inc., SAN DIEGO, CA; [2]Dept. of Neurosciences, Med. Univ. of South Carolina, Charleston, SC; [3]Applied Neurotechnology, Inc., Charleston, SC; [4]Ralph H. Johnson VA Med. Ctr., Charleston, SC; [5]Skaggs Sch. of Pharm. and Pharmaceut. Sci., UCSD, La Jolla, CA

Abstract: Pyroglutamate amyloid-beta peptides (pyroGluAbeta) lacking the first two N-terminal amino acids of full-length amyloid-beta 40 and 42 peptides and having a cyclized N-terminal glutamic acid (pyroGluAbeta3-40/42) may be the cause of Alzheimer's disease (AD) by catalyzing the formation of highly toxic amyloid-beta (Abeta) oligomers. Until now, the only means for reducing pyroGluAbeta production was to inhibit the enzyme glutaminyl cyclase, which catalyzes the cyclization of glutamic acid. In theory, beta-secretase could also be a potential upstream target but as yet neither the primary beta-secretase, BACE1, nor the alternative beta-secretase, cathepsin B (CatB), have been investigated for potential roles in producing pyroGluAbeta3-40/42. We show that deleting the CatB gene reduces pyroGluAbeta3-40/42, and overexpression of CatB increases pyroGluAbeta3-40/42 in APPLon mice. Importantly, that CatB deletion also improved memory deficits in those animals. But BACE1 gene deletion had no effect on pyroGluAbeta3-40/42 or memory in those mice. The APPLon AD mice were selected because they express the human amyloid precursor protein (APP) containing the wild-type (wt) beta- and London mutant gamma secretase site sequences, allowing CatB cleavage of the wt beta-site sequence that is expressed in most AD patients. The mice were also designed to express isoform APP-695 because brain neurons only express APP-695, Cat B beta-secretase activity occurs in neurons, and most amyloid-beta in AD patients is from brain neurons. In addition, we show that neuronal-like bovine cells, which have human wt APP processing, secrete pyroGluAbeta3-40 via constitutive and regulated secretion but secretory vesicles of the regulated secretory pathway produces most of the pyroGluAbeta3-40 and that the CatB inhibitor CA-074Me reduces pyroGluAbeta3-40 undergoing regulated secretion. These data strongly argue that CatB actively produces pyroGluAbeta3-40 and pyroGluAbeta3-42 and supports

pyroGluAbeta3-42 initiating the nucleation of Abeta oligomers in neurons that leads to neurotoxicity in AD. Interestingly, others recently concluded the opposite (Demattos 2012 Neuron 76:908). A likely reason for that is the transgene APP used in those other animals was not expressed by brain neurons and thus not available for CatB processing and CatB production of pyroGluAbeta3-40.42 could not occur. The important conclusions here are that CatB is a new target for reducing pyroGluAbeta3-40 and pyrogluAbeta3-42 and CatB inhibitors will thereby likely be effective AD therapeutics.

Title: Incidence and modulation of resting state subthalamic nucleus beta rhythm in Parkinson's disease

Authors: *L. A. SHREVE[1], A. VELISAR[1], N. M. SHANIDZE[1], B. C. HILL[1], C. KILBANE[1], J. M. HENDERSON[2], H. YU[2], H. BRONTE-STEWART[1];

Abstract: Beta frequency neural synchrony in the Local Field Potential (LFP), recorded from the subthalamic deep brain stimulation (STN DBS) lead may characterize the resting state in Parkinson’s disease (PD) and may be a useful signal for demand based DBS. However, some rest recordings failed to show increased LFP beta power, for unclear reasons. Objective: To determine the incidence of beta synchrony in PD rest recordings. Methods: Rest LFPs were

recorded from the STN DBS lead intra-operatively, after lead placement in 124 STNs from 62 PD patients. Concurrent inspection for any patient movement was performed via angular velocity recordings from contralateral limbs (arm and leg), accelerometer recordings from the head, continuous video recordings encompassing the full body and intra-operative notes. Raw data was scrutinized for artifacts, and each rest LFP spectrogram was aligned with the motion analysis and video recordings. Power spectral peaks were classified as being in the theta (5- <8 Hz), alpha (8- <13 Hz) and beta (13- <35 Hz) bands. Results: Mean pre-operative UPDRS III off (on) medication - 39.80 (20.67) +/- 11.98 (10.72) (+/- sd). 13 recordings were excluded due to artifact. Of the remaining 111, 105 (94.6%) revealed increased beta band power at rest. Of the 6 in which no beta peak was evident, 4 had clear evidence of concurrent consistent resting tremor and had peaks in the theta and/or alpha range, 1 of 6 had intermittent tremor and movement, and 1 of 6 had frequent movements that clinically appeared to be dyskinesias. Many rest recordings had evidence of intermittent tremor and/or movement, during which beta band power was transiently attenuated. These included 37 sides with intermittent tremor, 18 sides with voluntary or involuntary movement, and 13 sides with tremor and movement. Conclusions: In a large number of unmedicated PD patients with concurrent objective monitoring of movement, beta band synchrony was evident in 94.6% of STNs. In 4 of 6 recordings without beta synchrony, concurrent consistent tremor was evident along with LFP peaks in theta and/or alpha bands. In 2 of 6 there was intermittent tremor and/or dyskinesias. We suggest that tremor and/or movement may have modulated a resting beta band as we observed many cases where intermittent tremor or movement transiently attenuated underlying beta band synchrony. This data supports the hypothesis that beta band synchrony characterizes the true resting state of the STN in unmedicated PD. Care should be taken however to monitor the patient as involuntary or voluntary movements may modulate resting beta rhythm.

Title: Resolution of rest tremor reveals underlying subthalamic nucleus beta band synchrony in Parkinson's disease

Authors: A. VELISAR[1], L. A. SHREVE[1], B. C. HILL[1], H. YU[2], J. M. HENDERSON[2], *H. BRONTE-STEWART[1];

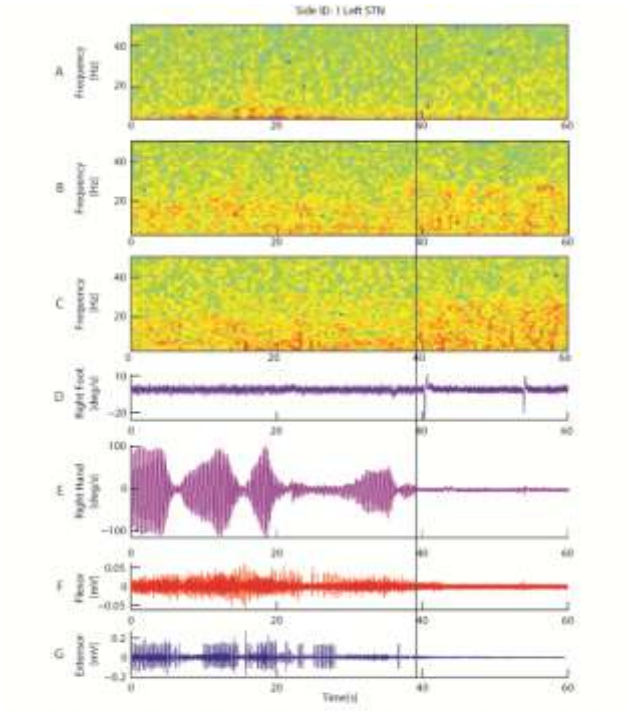
Abstract: While previous studies of local field potentials (LFPs) from the subthalamic nucleus (STN) during resting tremor in PD patients have revealed increased neural synchrony in low (5-13 Hz) frequency bands, we have occasionally noticed a reduction in the beta (13-35 Hz) band in this type of patient. Is the beta rhythm (13 - < 35Hz) is "missing" from the "rest" spectrum in tremor dominant PD subjects? Objective: to determine if tremor dominant PD is characterized by more beta frequency neural synchrony in periods of rest without tremor compared to tremor periods. Methods: LFP recordings from the deep brain stimulation (DBS) lead were made in 5 STNs from 3 PD subjects during which resting tremor resolved during the rest recordings. Concurrent movements/muscle activity of the contralateral limbs and the head were recorded using an accelerometer placed on the patient forehead, two angular velocity sensors placed on the hand and foot, and surface EMG electrodes placed on the wrist flexor and extensor muscles. The experiment was videotaped to check for movements not captured by the motion sensors and to confirm the presence or the cessation of tremor. Beta band power changes in the rest relative to tremor state were observed in spectrograms calculated using Short Fourier Transform with a moving window of 1 s long and 50 % overlap. The resulting frequency resolution was 1 Hz. Results: In all five recordings the resolution of tremor activity was associated with an emergence of power in the beta frequency band. Beta band power was greater in the rest no-tremor state than in the resting tremor state. Conclusions: resting tremor in PD modulates an underlying rest beta band rhythm. The dynamic modulation of the PD resting beta rhythm by rest tremor suggests that demand based DBS devices of the future would need to be programmed to respond to more than resting beta band power.



Beta rhythm emergence after hand tremor cessation, the vertical line shows the change in behavior state :

Title: Structural abnormalities of grey matter regions in Parkinson’s disease at baseline and 8-years follow-up

Authors: *C. WANG[1], L. CHAN[2], E. TAN[1,3], J. ZHOU[1];
[1]Neurosci. and Behaviour disorder, Duke-Nus Grad. Med. Sch., Singapore, Singapore; [2]Dept. of Diagnos. Radiology, [3]Dept. of Neurol., Singapore Gen. Hosp., Singapore, Singapore

Abstract: Introduction
Parkinson's disease (PD) is a progressive neuronal degenerative disorder characterized by neuron loss and changes in brain microstructure. Previous studies showed loss in grey matter volume (GMV) and disrupted white matter integrity in brain regions extending beyond nigrostriatal pathway[1,2,3]. The goal of this longitudinal study is to investigate brain structural changes in PD with a focus to delineate specific features of neuronal degeneration in PD progression from that of normal aging process, measured by both GMV and white matter integrity.

Methods
Whole brain T1 images and diffusion (12 directions) images were acquired from 39 cognitive intact PD patients and 52 age-matched healthy controls (HC) at baseline in 2005 with 8-years follow-up.
Subject-level GMV probability maps were extracted from T1 images and analyzed using voxel-based morphometry (VBM)[4]. Fraction anisotropy (FA) and mean diffusivity (MD) were obtained from preprocessed diffusion images[5] and analyzed using VBM and automated anatomical labeling (AAL) based regions of interest (ROIs) method[6] to evaluate group difference as well as longitudinal changes. Age, gender and ethnicity were entered as nuisance variables.

Results
At baseline, among the 90 ROIs, we found increased MD in PD group in orbital part of left inferior frontal gyrus ($P<0.05$, FWE corrected). This finding was further supported using VBM approach on whole-brain MD maps ($P<0.001$, extent threshold corrected).
At 8-years follow-up, using ROI approach, we found increased MD in more extensive brain regions, including orbital part of bilateral inferior frontal gyrus, bilateral superior temporal pole ($P<0.05$, FWE corrected), as well as regions in insula and ventral medial frontal gyrus ($P<0.005$, uncorrected). Consistent reduced FA in PD was identified in most regions where MD was increased ($P<0.05$, uncorrected). ROIs and VBM approaches showed converging results. Moreover, reduced GMV in PD was found in similar regions of increased MD, including left inferior frontal gyrus ($P<0.05$, FWE corrected) and right inferior frontal gyrus, bilateral temporal lobe and bilateral insula ($P<0.001$, extent threshold corrected).

Conclusion
Compared with healthy elderly, we found converging evidence of increased MD, decreased FA and reduced GMV of PD group in a more extensive brain network, including prefrontal cortex, insula, and temporal regions after 8 years follow up. Our result suggests higher rate of neuronal degeneration in the specific network in PD compared normal aging process.

Title: Synchronization of globus pallidus neurons to cortical oscillatory activity in humans with Parkinson's disease and primary dystonia

Authors: *N. C. SWANN[1], C. DE HEMPTINNE[1], E. RYAPOLOVA-WEBB[1], J. OSTREM[2], P. STARR[1];
[1]Neurolog. Surgery, [2]Neurol., Univ. of California, San Francisco, San Francisco, CA

Abstract: Introduction: Parkinson's disease (PD) is characterized by excessive synchronization of neuronal activity throughout the basal ganglia thalamocortical loop, constraining neurons in an inflexible pattern of activity. Similar abnormalities in synchronization have also been proposed for primary dystonia, but its pathophysiology is less well characterized.Methods: We investigated synchronization between basal ganglia and cortex by simultaneously recording globus pallidus unit discharge with cortical local field potentials (LFPs) in patients undergoing pallidal deep brain stimulator insertion for PD or primary dystonia in the awake state, at rest. Cortical LFPs were recorded over primary motor cortex, primary sensory cortex, and the superior parietal lobule using a 6 contact subdural electrocorticography strip electrode. Synchronization was assessed by pallidal spike timed averages of cortical LFPs and of cortical broadband gamma band activity.
Results: We recorded 31 pallidal units in 6 pts with PD and 33 units in 7 patients with primary dystonia. Seventeen pallidal units in PD and 21 pallidal units in primary dystonia were significantly synchronized to at least one cortical recording site. In dystonia, the predominant cortical site for synchronization was parietal cortex, while in PD, the predominant site was primary motor cortex. Prominent synchronization was observed at frequencies throughout the lower frequency range examined (4-50 Hz) for both disorders. Additionally, broadband gamma

amplitude (50-200 Hz) also varied significantly as a function of pallidal spike times for many cells, but patterns across cells were variable. This spike-locked broadband gamma activity was itself significantly coupled to lower frequency rhythms (4-50 Hz) in many cases (19 pallidal units in PD and 12 pallidal units in dystonia).
Conclusions: We have shown that marked synchronization exists between pallidal neurons and cortical LFPs in two movement disorders. The topography of cortex-basal ganglia synchronization may explain specific manifestations of movement disorders. In dystonia, excessive synchronization of the basal ganglia to parietal lobe structures could account for well-described abnormalities in sensory function, including two point discrimination and mental rotation. Whereas, in PD, the excessive synchronization to motor cortex may prevent dynamic chances in oscillatory activity necessary for movement initiation, resulting in akinesia or bradykinesia.

Sci., Rush Univ. Med. Ctr., Chicago, IL; [5]Dept. of Neurol., [6]Dept. of Applied Physiol. and Kinesiology, Univ. of Florida, Gainesville, FL

Abstract: Resting state fMRI is used in the current study to measure low frequency fluctuations in the blood oxygen level dependent signal to identify differences in functional connectivity (FC) between STN and primary motor cortex. The study included 20 healthy controls, 20 de novo Parkinson disease (PD), 19 moderate PD, 14 essential tremor (ET), 13 multiple system atrophy

(MSAp) and 10 progressive supranuclear palsy (PSP) subjects. All subjects taking medication were tested after overnight withdrawal from medication. Voxel-wise analyses compared each group with controls to identify significant clusters ($P < .05$, corrected) of difference. We placed a seed in the left subthalamic nucleus (STN) and drew a specific region of interest (ROI) in the ipsilateral primary motor cortex to focus on this area. De novo PD and moderate PD subjects both had significant clusters of increased FC between the left STN and the ipsilateral primary motor cortex. The finding of a strong correlation with ipsilateral primary motor cortex for moderate PD is consistent with a study by Beaudrexel et al. (2011), and we have extended this to de novo PD. We also found that the motor section of the Unified Parkinson's Disease Rating Scale was positively correlated with STN-motor cortex FC in subjects with PD ($r = 0.41$, $p < .009$). Within the ipsilateral primary motor cortex ROI, each group of subjects had elevated FC compared with controls (P's < .05, uncorrected). Moreover, there were significant clusters of increased FC in the SMA, contralateral primary motor cortex, and ipsilateral primary motor cortex for MSAp subjects, and increased FC in the contralateral primary motor cortex of PSP subjects. Significant clusters of reduced FC were found in the ipsilateral middle frontal gyrus for de novo PD, increased FC in the contralateral middle occipital gyrus for ET, decreased FC in the contralateral precuneus for MSAp, and decreased FC in the contralateral middle frontal gyrus for PSP. All subject groups also showed significant clusters of reduced FC in the contralateral medial frontal gyrus/cingulate. These results provide new findings that include: 1) ipsilateral STN-motor cortex FC is increased in de novo PD, ET, MSAp, and PSP, 2) MSAp and PSP have increased contralateral STN-motor cortex FC, and 3) STN-lateral prefrontal cortex FC is decreased in all forms of parkinsonism whereas the ET subjects has abnormal STN-occipital cortex FC. These results demonstrate the importance of the STN in regulating motor function in PD and highlight potential differences in the STN-cortical connectivity among PD, ET and atypical parkinsonisms.

Title: Resting-state functional network reorganization in Parkinson's disease

Authors: P. LAURO[1], *S. TINAZ[2], P. MALONE[1], C. LUNGU[1], M. HALLETT[2], S. HOROVITZ[2];
[1]Office of the Clin. Director, NIH/NINDS, Bethesda, MD; [2]Human Motor Control Section, NIH/NINDS, National Institute Of Health, MD

Abstract: Parkinson's Disease (PD) is a neurodegenerative disorder associated with motor and cognitive symptoms caused in part by dopaminergic denervation in frontostriatal circuits. Difficulty performing self-initiated tasks is characteristic of PD patients.
Implementation of self-initiated plans requires three steps, each facilitated by different resting state (rs) neural networks: 1) detection of motivational cues by the salience network (SN), attention through the frontoparietal network (FPN) to guide behavior, and execution of the motor plan by the sensorimotor network (SMN). We hypothesized that these networks will exhibit deficits in PD.
36 PD patients off dopaminergic medication for at least 12 hrs (age: 62.0 ± 8.0, 12 females, Hoehn & Yahr: 2.42 ± 0.5 (mild bilateral disease with mild imbalance)) and 36 age- and gender-matched healthy volunteers (HV) (age: 61.1 ± 7.0) were scanned.
T1-weighted anatomical images and functional MRI during rest with eyes closed (TR: 2s, TE: 30ms, flip angle: 70, FoV: 240, voxel size: 3.75x3.75x5mm) were collected in a 3T scanner for 6 min and 50 s. Functional images underwent standard preprocessing. Nuisance variables were regressed out. The signal was bandpass filtered (0.01-0.08 Hz).
SN, FPN, and SMN nodes were constructed using coordinates from previous studies (Seeley 2007 and Dosenbach 2010). BOLD time courses were extracted from each node and correlated with all other nodes in the network. Graph metrics including node connectivity strength (NS), betweenness centrality (BC) and global/local efficiency (GE/LE) were calculated using the Brain Connectivity Toolbox. Between-group comparisons are reported at $p < 0.05$ (2-sample t-test).
HV > PD results: 1) higher NS in all networks (SN: paracingulate, left frontal pole, and right ventrolateral prefrontal cortex (vlPFC); SMN: bilateral postcentral gyrus and right posterior insula (PI); FPN: right dorsal and ventral PFC, and right superior parietal), 2) higher BC (SN: left supplementary motor area (SMA) and pre-SMA; SMN: right PI; FPN: left posterior parietal), 3) higher GE in SMN and FPN.
PD > HV results: 1) higher LE (FPN: left dorsolateral premotor cortex (dlPMC)), 2) higher BC (SMN: right vlPMC).
Overall, PD patients off medication exhibit weaker rs-functional connectivity between key nodes in salience, attention, and execution networks, and less efficient functional integration of information in attention and execution networks. Of note, mesial premotor areas (SMA/pre-SMA) involved in self-initiated tasks seem to play a bridging role across networks in HV. In PD, this role is shifted to lateral premotor areas that are normally activated in externally-guided tasks.

Title: Spatial patterns of diffusion tensor imaging in Parkinson's disease

Authors: *S.-J. LIN[1,2], J. KOK[3], A. GRAG[3], M. F. BEG[3], M. J. MCKEOWN[1,2];
[1]Pacific Parkinson's Res. Ctr., Vancouver, BC, Canada; [2]Grad. Program in Neuroscience, Univ. of British Columbia, Vancouver, BC, Canada; [3]Sch. of Engin. Science, Simon Fraser Univ., Burnaby, BC, Canada

Abstract: Background:
Diffusion Tensor Imaging is a way to assess white matter integrity. While Parkinson's disease (PD) is normally associated with pathology in the basal ganglia, previous reports have suggested changes in fractional anisotropy (FA) values in frontal regions. Here we propose using independent component analysis (ICA) to examine the independent spatial patterns associated with FA changes in PD.
Methods:
Eighteen subjects (5 females; 13 males; average age 63.56; daily L-dopa dosage 400-1200 mg) with PD were included in this study. All patients signed the informed consent prior to beginning of the study. Anatomical and diffusion scans were performed in a Philips Achieva 3.0 Tesla MRI scanner at UBC Hospital. The anatomical image was a 3D T1-weighted scan with CLEAR homogeneity correction, covering a 256×170×200mm^3 field of view with a 256×170×256 voxel image. The diffusion weighted scans consisted of 32 scans with varying gradients and one B0 scan. The scans covered a 212×132×212 field of view with a 256×60×256 image, using a 96×96 scan matrix. Images were registered to a one image using a high-dimensional registration process. The FA data were smoothed with a 6x6mm kernel and then decomposed by the fastICA package in Matlab. The loadings on the spatial patterns across subjects were then correlated with clinical indices.
Results:
After correction for multiple comparisons, two subject-specific ICA loadings of the spatial components significantly correlated with clinical indices. One component, largely located over the primary motor cortex, demonstrated a positive correlation with daily L-dopa dosage. Another ICA component was significantly correlated with overall UPDRS scores, and the associated spatial map was located in the caudal brainstem.
Conclusions:
Our results suggest that FA values are significantly affected in Parkinson's disease is spatially-

specific patterns. The changes in the motor cortex suggest that requirements for greater medication may be dependent upon microstructural changes in the motor cortex in PD.

Title: Functional connectivity changes in early-stage Parkinson's disease

Authors: *P. BOORD, E. COLLINS, M. ASKREN, T. J. GRABOWSKI, Jr;
Radiology, Univ. of Washington, Seattle, WA

Abstract: Introduction
Cognitive impairment (CI) in Parkinson's disease (PD) is often present at the time of initial diagnosis; becomes more frequent and pronounced in later stages of disease; and commonly culminates in dementia. The basis for this impairment, however, remains unclear. Functional connectivity (FC) differences measured by functional MRI (fMRI) have been observed in PD in default and cortico-striatal networks, but FC differences in attention and salience networks have not been reported. We report here FC differences in these networks in early-stage PD, in the absence of behavioral differences and gray matter (GM) volume atrophy.
Method
Medicated, early-stage, cognitively normal PD patients (n=14, age=62.4, SD=8.7, most with right-lateralized weakness) were compared to healthy controls (HC; n=10, age=56.6, SD=7.0). Resting state fMRI (rsFMRI) was acquired for 12 mins with eyes open. The Attention Network Test (ANT; Fan et al 2002) was administered in six blocks of six minutes duration. Two scanning sessions were acquired in most subjects (n=23) and the statistical maps were averaged across sessions prior to higher order analysis.

rsFMRI mean time courses were extracted from seed regions in the default mode (DMN), dorsal attention (DAN; Power et al 2011) and salience (SAL; Menon and Uddin 2010) networks. Seed-based FC maps were z-transformed. GM volume was estimated using a T1 MPRAGE image and voxel-based morphometry (VBM). PD and HC were compared for differences in FC and GM volume using higher order analysis, with statistical maps thresholded at the cluster level (pFWE-corr < 0.05; extent threshold > 50 voxels).

Results

A widespread FC reduction was observed in PD in the medial frontal wall relative to left and right anterior intraparietal sulcus (aIPS) and anterior cingulate. FC was also reduced between left aIPS and left caudate, and right frontal insular cortex and cuneus/precuneus. No significant reductions in FC were observed in the DMN. No differences in attention measures (alerting, orienting, executive) were observed between groups in the ANT. GM volume reductions were observed in PD, chiefly in left frontoparietal cortex, with significance at the set level (8 clusters; $p = 0.015$), but not at individual clusters.

Conclusion

Significant reductions in FC can be observed in early-stage PD, even in the absence of significant reductions in GM or changes in attention measures. FC reductions between frontal cortex, DAN and SAL might underlie CI observed in later stages of PD, and these connectivity patterns may serve as useful biomarkers to test and develop treatments for cognitive decline in PD. Future work in our lab will aim to investigate these proposals.

Kinesiology, Univ. of Michigan, Ann Arbor, MI; [6]Sch. of Medicine: Neurol., Univ. of Colorado Denver, Denver, CO; [7]Ctr. for Cognitive Neurosci., Duke Univ., Durham, NC

Abstract: Parkinson's disease is a progressive neurodegenerative disorder associated with both motor and cognitive impairments. We have previously reported altered resting state functional connectivity between the basal ganglia and the cerebral cortex in Parkinson's disease, including hyperconnectivity in Parkinson's patients OFF medication compared to healthy controls that is down-regulated by L-DOPA medication (Kwak et al., 2010). Although the basal ganglia are a primary target of degeneration in Parkinson's disease, other structural and functional brain changes involving the cerebellum have been observed. For instance, it has been suggested that Parkinson's patients may recruit cerebellar networks to compensate for striatal degeneration and dopamine depletion (e.g., Palmer et al., 2010). Moreover, Liu et al. (2013) found evidence for altered resting state functional connectivity of the dentate nucleus of the cerebellum in Parkinson's disease, with decreased cortical default mode connectivity and increased compensatory cerebellar-cerebellar connectivity.

We extend this research by implementing a lobule-based cerebellar resting state functional connectivity analysis (see also Bernard et al., 2012) in Parkinson's patients and by comparing connectivity in patients ON and OFF their medication and healthy controls. A lobule-based approach allows us to examine connectivity between anatomically disparate regions of the cerebellum. Twenty-five Parkinson's patients and twenty-three controls of similar age and gender completed structural and functional magnetic resonance imaging (MRI) scans. Functional scans were collected at rest, while participants viewed a fixation cross for 8 minutes. Outside the scanner all participants completed a battery of motor and cognitive assessments.

Results indicate greater cerebellar functional connectivity in Parkinson's patients OFF medication than ON medication between Right Lobule VI and areas such as the precuneus and the supramarginal gyrus. Additionally, results indicate hypoconnectivity in Parkinson's patients ON medication compared to healthy controls. For example, there is evidence for reduced cerebellar functional connectivity with Right Crus I and the bilateral middle frontal gyrus, with Right Crus II and the bilateral middle frontal gyrus and the precentral gyrus, and with Right Lobule VI and the precentral gyrus, postcentral gyrus, inferior parietal, and superior temporal regions. We will further explore the relationships between cerebellar resting state functional connectivity and behavior to determine if the observed effects are pathological or compensatory.

Title: Neuronal oscillation patterns in the subthalamic nucleus and the ventrolateral thalamus in patients with Parkinson's disease

Authors: *P. ZHUANG[1], M. HALLETT[2], S. GUO[1], L. HE[1], Y. ZHANG[1], J. LI[1], Y. LI[1]; [1]Xuanwu Hosp, Capital Med. Uni, Beijing, China; [2]HMCS, NINDS, NIH, Bethesda, MD

Abstract:

Background: Increased oscillatory firing and synchrony between neurons within the basal ganglia and thalamus appear to play a key role in the pathophysiology of Parkinson's disease (PD).

Objective: To explore oscillatory activity in the STN and the Vop/Vim in patients with PD.

Methods: Forty-three PD patients (male: 28; female: 15; age 57.6 ±10.3 years) were studied. All patients had tremor, rigidity and bradykinesia. 23 patients underwent implantation of a deep brain stimulation (DBS) electrode into the STN and 20 patients underwent lesioning or implantation of a DBS electrode into the Vop/Vim. Microelectrode recordings were performed in the STN or Vop/Vim, and the EMG of the body side contralateral to surgery was recorded simultaneously. Single units were identified. The interspike interval (ISI) and coefficient of variation of ISI were calculated. Oscillatory patterns were evaluated using power spectral analysis with the Welch method.

Results: A total of 178 neurons were identified from the STN and 190 neurons were identified from the Vop/Vim. Spectral analysis of these neurons showed that there were three types of neuronal activity: (1) neurons with tremor frequency oscillations which displayed burst activity at tremor frequency concurrently with limb tremor. Their mean oscillation frequency was 4.2±0.7 Hz (with a range of 3.8-6 Hz), defined as the tremor frequency band oscillation (TFB) neurons. (2) Neurons with high-frequency oscillations (>8 Hz). Their mean oscillation frequency were 21.5±8.6 Hz (with range of 8-30 Hz), defined as the β frequency band oscillation (βFB) neurons. (3) Neurons with no oscillatory activity, defined as non-oscillation neurons. Few neurons (>30 Hz) displaying oscillatory activity in the gamma band were not further analyzed in the present study. Of all STN neurons with oscillations (n=59), 29% neurons were with TFB oscillation and 71% neurons were with βFB oscillation. Oppositely, of total Vop/Vim neurons with oscillations (n=31), 77% neurons had TFB oscillation whereas 23% neurons had βFB oscillation. Further analysis found that the density of neurons with TFB oscillation was almost twice in Vim than that in

Vop ($p<0.05$). Furthermore, a majority of neurons with βFB oscillation (20 of 25) was found in Vop.
Conclusion: Neurons with βFB oscillation were observed in the STN and Vop (presumed pallidal relay nucleus) supporting the prediction that the basal ganglia is involved in parkinsonian bradykinesia/rigidity. Neurons with TFB oscillations were mainly localized in the Vim (presumed cerebellar relay nucleus) supporting the view that the Vim is involved in tremor generation.

Title: Differences in dopaminergic disruption between dementia with Lewy bodies and Parkinson's disease

Authors: *K. OKITA[1], K. ISHII[2], K. ODA[2], M. SAKATA[2], J. TOYOHARA[2], M. IYO[4], K. KANEMARU[5], S. MURAYAMA[3], K. ISHIWATA[2];
[1]UCLA Lab. of Mol. Neuroimaging, Los Angeles, CA; [2]Positron Med. Ctr., [3]Dept. of Neuropathology, Tokyo Metropolitan Inst. of Gerontology, Tokyo, Japan; [4]Dept. of Psychiatry, Chiba University, Grad. Sch. of Med., Chiba, Japan; [5]Dept. of Neurol., Tokyo Metropolitan Geriatric Hosp., Tokyo, Japan

Abstract: Objective: Parkinson's disease (PD) and dementia with Lewy bodies (DLB) are neurodegenerative disorders sharing common pathological feature of Lewy bodies. We characterized the difference in the nigrostriatal degeneration patterns between these diseases presenting equivalent parkinsonism severity. Further, we investigated the relationships between dopaminergic dysfunction and motor and cognitive dysfunction severity.
Methods: We studied 28 PD patients, 22 DLB patients, and 8 healthy subjects selected based on diagnostic guidelines with additional inclusion/exclusion criteria. Further, we incorporated neuroimaging findings. Motor and cognitive symptoms were scored using the unified Parkinson's disease rating scale and Mini-Mental State Examination(MMSE). PET scans were performed using ^{11}C-labeled 2β-carbomethoxy-3β-(4-fluorophenyl)-tropane (^{11}C-CFT) and ^{11}C-labeled raclopride (^{11}C-RAC) as indices of pre- and post-synaptic dopaminergic functions,

respectively.
Results: In the caudate and anterior putamen, significantly lower binding of ^{11}C-CFT was observed in DLB than in PD in all Hoehn and Yahr (H&Y) stages. In the posterior putamen, the binding of ^{11}C-CFT was significantly lower in DLB in the H&Y stage 2. In contrast, there is no significant difference binding of ^{11}C-RAC between these diseases in both of caudate and putamen. A significantly lower caudate-to-putamen ratio of ^{11}C-CFT binding was observed in DLB than in PD ($p < 0.05$). A positive correlation between MMSE and ^{11}C-CFT binding was observed in the caudate among PD and DLB patients ($\rho = 0.54$, $p < 0.001$).
Conclusion: Thus, more severe dopaminergic dysfunction was shown in DLB patients than in PD patients with the same level of motor dysfunction, suggesting modulatory mechanisms of motor symptoms in DLB. Further, dopaminergic function in the caudate is likely associated with cognitive impairment of PD and DLB subjects.

Title: Parkinson’s disease patients: Plasma cytokine profile

Authors: *C. WAKADE[1], J. MORGAN[2], R. LUCAS[3], S. SRIDHAR[3], R. SUHAG[4], R. CHONG[5];
[2]Neurol., [3]Vascular Biol. Ctr., [4]IMMAG, [5]Physical Therapy, [1]Georgia Regents Univ., Augusta, GA

Abstract: Neuroinflammation plays a crucial role in the pathogenesis of Parkinson’s disease (PD). The systemic inflammation is known to contribute to the ongoing neurodegeneration in PD and is also a sequel to PD symptoms in early and late stages (1). Pro and anti-inflammatory cytokines levels may associate with the severity of the PD symptoms. We examined the plasma levels of thirteen cytokines in PD patients, age-matched controls, and young healthy controls: GM-CSF, IFN-γ, IL-10, IL-12, IL-13, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, and TNF-α. Milliplex MAP kit was utilized to measure these cytokines using human cytokine magnetic beads at 0.08 - 1.01 pg/mL sensitivity. Moderate PD patients demonstrated significantly higher

levels of IL-4 compared to all elderly controls (p=0.016). IL-6 was higher in moderate PD patients compared to young healthy controls (p=0.026). Levels of IL-7 were higher in moderate PD patients (p=0.002), both mild and moderate PD patients (p=0.007) and all elderly controls (p=0.006) compared to young healthy controls. Similarly, all the PD patients demonstrated higher levels of IL-8 (p=0.047) and TNF-α (p=0.025) compared to all young healthy controls. In conclusion, cytokine levels in PD, particularly IL-7 need to be further explored using larger samples.

Title: Amazing astrocytic activation in parkinsonism

Authors: *G. CHARRON[1], E. DOUDNIKOFF[2], N. SOLARI[2], M.-H. CANRON[2], J. BAUFRETON[2], C. VEGA-ROÏATTI[2], E. BOUE-GRABOT[2], S. OLIET[3], E. BEZARD[2]; [1]IMN CNRS UMR 5293, Bordeaux, France; [2]IMN UMR 5293, Bordeaux, France; [3]Neurocentre Magendie INSERM U862, Bordeaux, France

Abstract: Dopamine (DA) deprivation in Parkinson's disease (PD) provokes complex and multiple changes in striatal DA target neurons that contribute to development of characteristic motor disorders such as bradykinesia, rigidity and resting tremor and later on of dyskinesia. The mechanisms triggering and/or contributing to the morphological and functional modifications affecting the basal ganglia (BG) network remain elusive and we consider too premature the current efforts without gaining an intimate knowledge of the whole synaptic organization at the striato-pallidal level. Puzzlingly enough, the role of astrocytes in such complex pathological changes has almost remained untouched. The current concept of BG organization and function excludes (so far) the most numerous cells in the brain, i.e. the astrocytes. For decades, astrocytes have been regarded as passive partners of neurons in the central nervous system, but this view has been challenged recently and they are now integrated in the concept of "tripartite synapse",

the structure consisting of pre- and post-synaptic elements of the synapse and an associated astrocyte process, supporting the idea that astrocytes participate actively in information processing. Gliotransmission includes the release of many chemical transmitters from astrocytes, including classical transmitters (glutamate, GABA, ATP and D-serine), peptides and cytokines using diverse mode of release (vesicular and non-vesicular). Although the past decade has seen an explosion of research on role of neuron-astrocyte interactions in the control of brain function, the role(s) of astrocyte in PD and LID remains to be investigated. Thus, the present work, undertaken in three animal models of PD as well as in human PD brains: (i) unravels the yet unknown plastic astrocytose in the parkinsonian and dyskinetic basal ganglia (ii) in the absence of gross variation in gliotransmitter levels; characterizes the connectivity of the astrocytes through expression of the connexins (iii) between themselves and (iv) with cortico-striatal and striatopallidal synapses.

Title: Neurotoxic insults upregulate Prokineticin-2 levels in Parkinson’s disease models and in PD patients

Authors: M. L. NEAL, R. GORDON, H. JIN, V. ANANTHARAM, *A. G. KANTHASAMY, A. KANTHASAMY;
Biomed Sci, Iowa Ctr. for Advanced Neurotoxicology, Iowa State Univ., AMES, IA

Abstract: Prokineticin 2 (PK2) is a secreted chemokine-like protein that mainly functions in the brain for olfactory bulb biogenesis and circadian rhythms. We previously demonstrated that PK2 is up regulated in dopaminergic neurons upon neurotoxic insults, as determined by targeted qPCR array analysis. Additionally, administration of recombinant PK2 protected against MPP+-induced dopaminergic neuronal cell death, suggesting a pro-survival role of PK2 in dopaminergic neurons. In order to further define the role of PK2 in Parkinson’s disease (PD) neuropathology, herein we performed immunohistochemical and Western blot analyses of

postmortem midbrain tissues from human PD cases and age-matched control subjects. Moreover, quantitation of serum PK2 levels using ELISA revealed lower serum concentrations of PK2 in PD patients as compared with their respective controls. In contrast, no significant change in serum PK2 levels was observed between PD and control samples. In the next set of experiments, we sought to investigate the expression profile of PK2 in animal models of PD. Time-course analyses of PK2 in the MPTP-induced mouse model of PD showed a time-dependent up regulation of PK2 in the nigral tissues, with maximal PK2 levels achieved at 12 hr post-MPTP injection. Immunohistochemical studies further confirmed that MPTP-induced PK2 upregulation in the nigral dopaminergic neurons. We also used the PK2-eGFP GENSAT mouse model to characterize the expression level of PK2 following MPTP challenge. Our results showed a dramatic increase in PK2 expression in the MPTP-treated SN as compared to controls. At the cellular level, we also found that the PK2 receptors, PKR1 and PKR2, are expressed in both neuronal and glial cells. Functional studies revealed that stimulation of PK2 receptors induces an increase in intracellular Ca2+ and promotes glial migration and proliferation. Collectively, our findings provide a potentially novel correlation between PK2 signaling and dopaminergic neuronal survival in an MPTP model of PD and midbrains from PD patients. The results suggest that PK2 signaling may be pivotal in dopaminergic neuronal survival, thereby implicating this secretory protein in PD pathogenesis (supported by NIH grant 078327).

Title: Alpha-synuclein in the colonic submucosa of PD compared to MSA patients

Authors: *H. B. DODIYA, K. M. SHANNON, A. KESHAVARZIAN, J. H. KORDOWER; Neurosci. Dept., Rush Univ. Med. Ctr., Chicago, IL

Abstract: Parkinson disease (PD) diagnosis depends on the clinical recognition of motor signs including tremors, rigidity and bradykinesia. But these motor symptoms do not appear until the advanced stage of degenerative processes into the mid-brain with at least 40-60% cell loss in the substantia nigra. With a potentially long premotor course, there is an urgent need to develop

premotor biomarkers. Recently, our group has demonstrated α-synuclein pathology in colon samples prior to onset of PD (2-5 years before first motor PD symptom). Our group has also shown α-synucleinopathy in the colonic submucosa samples of early untreated PD cases (n=10) compared to the healthy controls (n=23) and inflammatory bowel disease (IBD) patients (n=23), suggesting specificity of alpha synuclein pathology within the colon samples of PD cases compared to IBD and controls. To establish whether a similar pathological expression of α-synuclein occurs in the colon of other synucleinopathies, the current study compared α-synuclein expression in colon samples of PD to that of multiple system atrophy (MSA) and healthy controls. Like PD, MSA is a synucleinopathy although α-synuclein is principally a major component of oligodendroglia in this disease and not neurons. The occurrence of glial cell inclusions (GCIs) and the filamentous aggregation of α-synuclein in the neurons of several brain regions are potentially a synergistical process that may cause neuronal degeneration in MSA. In the current study, we collected biopsy of the distal sigmoid colon samples (PD: n=28, MSA: n=6, Controls: n=8) using unprepped flexible sigmoidoscopy procedure. Immunohistochemistry studies for α-synuclein were performed on these biopsy samples. From all PD cases (n=28), 18 showed α-synuclein staining in colonic submucosa. The presence and intensity of α-SYN staining was reviewed and rated in a blinded manner using 5 point scale system (Shannon KM, 2012). Using the 0-4 point scale (0 = no staining and 4 = robust staining), in PD (n=28): 10 cases had no staining, 4 cases had 1+, 2 cases had 2+, 5 cases had 3+ and 7 cases had 4+ scores. Compared to PD cases, in MSA (n=6): 5 had no staining, 1 had 1+, and none had 2+, 3+, or 4+ scores. While in Control (n=8): 4 had no staining, 4 had 1+ and none had 2+, 3+, 4+ scores. These data indicate that α-synuclein staining is specific for PD and not seen in other synucleionopathies such as MSA or in IBD (Shannon et al, 2012) or age-matched controls.

Title: The NINDS Repository Biomarkers Discovery Collection: a public resource of biomaterials for neurodegenerative disease research

Authors: *M. J. SELF[1], K. GWINN[2], M. SUTHERLAND[2], C. A. PÉREZ[1], W. MUHAMMAD[1], G. M. BALABURSKI[1], J. GILROY[1], M. FRASIER[3], L. VINCENT[3], R. A.

CORRIVEAU[2], C. TARN[1];
[1]NINDS Repository, Coriell Inst. For Med. Res., Camden, NJ; [2]Natl. Inst. for Neurolog. Disorders and Stroke-NIH, Bethesda, MD; [3]Michael J Fox Fndn., New York, NY

Abstract: Neurological disorders present a massive challenge to healthcare systems globally. Identification of novel and reliable biomarkers that would allow for more efficient diagnosis, monitoring of disease onset and progression, and assessment of response to therapeutics, holds immense promise for improving clinical outcomes in individuals affected with disorders such as Parkinson's Disease and Huntington's Disease. The National Institute of Neurological Disorders and Stroke (NINDS) Repository at the Coriell Institute for Medical Research, also known as the NINDS Human Genetics Resource Center, has an overall mission of accelerating discovery of causes and risks for neurological disease by sharing biomaterials and de-identified clinical data. As a centralized facility for storage, processing, and distribution of biofluids (cerebrospinal fluid, plasma, serum, whole-blood, urine) and nucleic acid (DNA and RNA), the NINDS Repository serves as an integral component in the effort to identify and validate biomarkers of neurological disease. The establishment of large collections of biological samples obtained longitudinally from both affected and neurologically healthy individuals should prove invaluable for furthering investigation of biochemical markers via transcriptomic, proteomic, or metabolomic approaches. Currently the NINDS Repository collects samples under multiple NINDS sponsored biomarker initiatives including the Parkinson's Disease Biomarkers Program (PDBP) and the Neurobiological Predictors of Huntington's Disease study (PREDICT-HD), as well as a jointly sponsored study (BioFIND) on Parkinson's Disease in collaboration with the Michael J. Fox Foundation. The NINDS Repository aims to: (i) ensure that samples collected for biomarker discovery are of premier quality by collaboratively establishing unified standards of sample collection; (ii) provide rapid feedback to clinical sites regarding sample appearance and quality; (iii) maintain secure, high quality sample storage conditions with real-time monitoring and recording systems; (iv) perform standardized laboratory processing and quality assurance using validated operating procedures. The NINDS Repository thus provides a vital resource for research designed to discover and validate biomarkers of neurological disorders. Biomarker discovery samples are available upon request either directly from the NINDS Repository web catalog (http://ccr.coriell.org/NINDS), or via NIH-sponsored resources with links to the online catalog.

Title: Cortical thinning and subcortical white matter changes in Parkinson's Disease

Authors: KOSHIMORI[1,2], B. SEGURA[1], L. CHRISTOPHER[1,2], A. E. LANG[2], S. HOULE[1], A. P. STRAFELLA[1,2];
[1]Res. Imaging Ctr., Ctr. For Addiction and Mental Hlth., Toronto, ON, Canada; [2]Toronto Western Hosp. & Res. Inst., Toronto, ON, Canada

Abstract: Background: The pathology of Parkinson's disease (PD) involves widespread brain areas beyond the nigrostriatal dopamine pathway and produces motor and non-motor symptoms. Whole brain analysis is needed to understand the complexity of the disease. Structural neuroimaging studies have demonstrated changes in gray and white matter in PD patients: however, few studies have investigated both gray and white matter changes in the same group of the patients. Purpose: The present study investigated gray and white matter changes of whole brain in PD patients using MRI. Specifically, we compared cortical thickness, subcortical gray matter volume, and microstructure of white matter of a group of PD patients with those of healthy controls. Methods: Cortical thickness maps and the values of subcortical gray matter volume were derived from T1-weighted images using FreeSurfer. Fractional anisotropy (FA) and mean diffusivity (MD) maps were derived from DWI images using FSL. We also correlated each imaging data with severity of the motor symptoms measured using Unified Parkinson's Disease Rating Scale (UPDRS) III, duration of disease, and cognition measured by Montrreal Cognitive Assessment (MoCA) in PD group. Results: In the cortical analysis, PD group showed significant cortical thinning in left superiofrontal gyrus ($p < 0.032$, corrected) and postcentral extending anteriorly precentral and caudal middle frontal gyri ($p < 0.001$, corrected) compared with HC group. In the white matter analysis, PD group showed significantly higher MD values in multiple white matter tracts including bilateral inferior longitudinal fasciculi, bilateral uncinate fasciculi, forceps minor, bilateral anterior thalamic radiation, bilateral superior longitudinal fasciculi, body of the corpus callosum, and left corticospinal tract ($p < 0.05$, corrected) compared with HC group. Furthermore, in PD group, FA values showed significant negative correlation with disease duration in the left anterior thalamic radiation, body and part of splenium of corpus callosum, bilateral corticospinal tracts, left superior longitudinal fasciculus, and left inferior longitudinal fasciculus ($p < 0.05$, corrected). Conclusions: Our data demonstrate that PD patients show cortical and subcortical structural brain changes and white matter changes are associated with the disease duration.

Title: Cerebellar networks with basal ganglia: Degeneration of cerebello-pallidal and nigro-striatal projections in PD

Authors: E. A. PELZER[1], A. HINTZEN[1], C. MELZER[1], A. SCHÖNEBERGER[2], D. Y. VON CRAMON[1], L. TIMMERMANN[2], *M. TITTGEMEYER[1];
[1]MPI For Neurolog. Res., Cologne, Germany; [2]Univ. Hosp. of Cologne, Cologne, Germany

Abstract: Neuroanatomical studies using virus transneuronal tracers in macaque monkeys recently demonstrated that substantial interactions exist between basal ganglia and cerebellum (Bostan et al., 2013). To which extent these interactions are present in the human brain remains unclear; however, these connections are thought to provide an important framework for understanding cerebellar contributions to manifestation of basal ganglia disorders, especially with respect to pathogenesis in Parkinson's disease (PD; cf., Helmich, 2012; Wu and Hallet, 2013).
In this study we apply in vivo connectivity analysis following diffusion MRI and tractography to investigate pathological changes in PD in the dentato-pallidal and nigro-striatal pathways.
To this end, 3 T diffusion and structural MRI images were acquired in 12 right-handed, non-demented male PD patients (mixed type=6; akinetic-rigid =6) and 12 age-matched controls (mean age: 63 y). All patients underwent L-Dopa-therapy (LEDD: 678 mg/d, the UPDRS-III motor score revealed on average 16 points after a standardized levodopa dose of 200 mg, and on average 29 points without medication). All MR-images were analysed with FSL 5.0.2 (http://fsl.fmrib.ox.ac.uk/fsl/). Masks of dentate nucleus, pallidum, thalamus, caudate nucleus, putamen and substantia nigra were outlined in MNI standard space. Each mask was used as seed and target, respectively, for tractography; resulting connectivity values were statistically analysed in correlation to disease severity.
We find that: (1) diffusion MRI offers the possibility for an in vivo quantification of basal ganglia circuitry; (2) PD patients have reduced nigro-striatal connections; (3) significant

alterations in intrathalamic areas with projections from both cerebellar and pallidal pathways; (4) akinectic-rigid patients show a significant loss in dentato-pallidal connectivity, pointing towards a retrograde degeneration in these pathways.
This is one of the first studies indicating in vivo retrograde degeneration in basal ganglia satellite systems of PD patients.

Title: Functional and structural neuroimaging of Parkinson’s disease and the parkinsonian variant of multiple system atrophy

Authors: *P. J. PLANETTA[1], P. SHUKLA[1], A. S. KURANI[3], D. M. CORCOS[4], C. L. COMELLA[5], N. R. MCFARLAND[2], M. S. OKUN[2], D. E. VAILLANCOURT[1];
[1]Applied Physiol. and Kinesiology, [2]Neurol., Univ. of Florida, Gainesville, FL; [3]Bioengineering, [4]Kinesiology and Nutr., Univ. of Illinois at Chicago, Chicago, IL; [5]Neurolog. Sci., Rush Univ. Med. Ctr., Chicago, IL

Abstract: Parkinson’s disease (PD) and the parkinsonian variant of multiple system atrophy (MSAp) are progressive neurodegenerative disorders that can be difficult to differentiate due to their overlapping motor features. While magnetic resonance imaging (MRI) techniques have revealed structural differences in PD and MSAp, the functional differences between these

diseases have not been assessed across the entire brain. To this end, the present study used structural MRI and task-based functional MRI (fMRI) at 3 T in 14 MSAp patients, 14 PD patients, and 14 age-matched controls. fMRI examined the blood oxygenation level-dependent (BOLD) signal during a precision grip force task that has been shown to activate the basal-ganglia-thalamo-cortical circuit in healthy individuals. Behaviorally, the MSAp group was slower to reach steady-state force amplitude than controls and both patient groups were slower to release force from steady-state amplitude back to baseline. Voxel-wise analyses were performed on the whole-brain and cerebellum normalized fMRI data using family wise error correction ($p <$ .05). The results showed that the PD group was hypoactive in the putamen, globus pallidus, thalamus, primary motor cortex, dorsal premotor area, and pre-supplementary motor area compared to controls. In the cerebellum, the PD group had reduced activity in lobule VI and crus I and increased activity in lobule V and crus I. Compared to controls, the MSAp group was also hypoactive in the putamen, globus pallidus, and thalamus, but showed only one other area of hypoactivity, in cerebellar lobule VI. In addition, the MSAp group was hyperactive in the inferior parietal lobule, lingual gyrus, and several cerebellar areas such as lobules VIIIa, V, VI, crus I, and vermis. When the PD and MSAp groups were compared directly, there were no BOLD activity differences in the basal ganglia or thalamus, but the MSAp group was hyperactive in primary sensorimotor cortex, dorsal and ventral premotor areas, insula, and throughout the cerebellum. In summary, this study showed that PD and MSAp have similar functional changes in the basal ganglia and thalamus and differential changes in the cortex and cerebellum during a precision grip force task. The PD group had reduced BOLD activity in the basal ganglia, thalamus, and cortex, and both reduced and increased activity in the cerebellum. The MSAp group also had reduced activity in the basal ganglia and thalamus, but increased activity in the cortex and cerebellum. Currently, we are performing voxel-based morphometry on the structural MR images to investigate how these functional changes relate to brain atrophy.

Title: The effects of MR field strength on connectivity-based segmentation of the SN/VTA using diffusion tensor imaging at 3 and 7-tesla

Authors: *M. BETTS[1], J. KAUFMANN[2], M. KANOWSKI[2], K. NEUMANN[1], P. SCHULZE[1], E. DÜZEL[1,3];
[1]German Ctr. For Neurodegenerative Dis. (DZNE), Magdeburg, Germany; [2]Dept. of Neurology, Univ. Hosp. of Magdeburg, Otto-von-Guericke Univ. Magdeburg, Magdeburg, Germany; [3]Otto-von-Guericke-University, Inst. of Cognitive Neurol. and Dementia Res., Magdeburg, Germany

Abstract: The dopaminergic SN/VTA plays a key role in numerous cognitive functions such as reward processing, learning and memory. There is much interest in the neuroimaging community to delineate subregions of the SN/VTA as this complex is differentially affected by both health (e.g. normal aging) and disease (Parkinson's disease). One approach is to use diffusion tensor imaging (DTI) with probalistic tractography to segment structures based on their known regional connectivity (Behrens & Berg 2005; Chowdhury et al., in press). In this study we aim to use DTI-derived connectivity maps to subdivide the SN/VTA into dorsomedial and ventrolateral subregions based on connectivity to the ventral and dorsal striatum respectively.
Using ultra high-field DTI at 7-tesla (T) in parallel with 3T DTI, we seek to determine the benefit of higher magnetic field strength with respect to nigro-striatal connectivity. Whilst signal-to-noise (SNR) for DWI-derived measures has previously been reported to be generally higher at 7T (Polders et al., 2011), higher field strengths may also be more prone to eddy current distortions, magnetic susceptibility gradients and signal loss, offsetting potential SNR advantages (Zhan et al., 2012).
Healthy young subjects were scanned at 3T using 30 (+ 1 b0 image) and 64 diffusion directions (+ 7 b0 images) at 1.8mm isotropic resolution using alternative diffusion gradient values and at 7T using 64 diffusion directions (+ 1 b0 image) at 1.4mm isotropic resolution, obtaining the average of two acquisitions. We examined how scanner field strength affects SNR of non-diffusion (b0) reference images, number of fibers, connectivity measures, multi-channel reconstruction methods (sum-of-squares and adaptive combined at 3T) and DTI-derived diffusion metrics. SN segmentation was performed using magnetization transfer, proton density and susceptibility weighted imaging to explore how each contrast may impact nigrostriatal connectivity.
At 3T, improved SNR in both the SN and striatal target regions was observed with increasing number of diffusion bvals and directions using adaptive-combined reconstruction. Whilst a decrease in SNR was observed at 7T, a substantial increase in fiber projections from the SN to the ventral and dorsal striatum was found suggesting an increase in nigrostriatal connectivity with respect to 3T. No differences in quantitative diffusion metrics were observed at higher field strength.
Our provisional findings suggest greater connectivity observed at higher resolution using 7T may be beneficial in the parcellation of the SN/VTA, to obtain a more fine-grained understanding of the pathological changes occurring in aging and disease.

Title: Characterizing PD tremor using smartphone measurements of patient daily behavior

Authors: *M. YAZDANI, G. G. GAMBLE, W. C. LENNON, Jr.;
UCSD, La Jolla, CA

Abstract: Tremor is a common symptom of many movement disorders, including Parkinson's Disease (PD) and Huntington's Disease. Furthermore, the stage of a movement disorder is often tightly correlated with the severity of tremor. A key element, therefore, in understanding the severity of a movement disorder (and to help aid its treatment) is to quantify the dynamics of tremor symptoms. Such quantification can be used as feedback of the motor disorder severity, which can then supplement an appropriate treatment (such as patient specific treatments, quantifying the efficacy of treatments, telemedicine, etc.). In this study we quantify the symptoms of PD by developing computational tools based on dynamic measurements. We use a dataset provided by the Michael J. Fox Foundation that monitors daily behavior of PD patients and control subjects using a smartphone. Using machine learning techniques to classify activities with measured acceleration features, we are able to isolate and parse the various behaviors of the PD patients and control subjects (such as walking, remaining sedentary, etc). By isolating behaviors, we report our preliminary results on quantifying the relationship between tremor severity and the stage of PD using the Unified Parkinson's Disease Rating Scale (UPDRS). This study strongly supports the use of smartphones as an aid for clinical applications by capturing the daily behavior of patients.

Title: Deep brain stimulation tractography-activation models developed with 7T MRI data

Authors: *K. GUNALAN[1], A. CHATURVEDI[1], Y. DUCHIN[2], G. SAPIRO[3], N. HAREL[2], C. MCINTYRE[1];
[1]Biomed. Engin., Case Western Reserve Univ., Cleveland, OH; [2]Radiology, Univ. of Minnesota, Minnesota, MN; [3]Electrical & Computer Engin., Duke Univ., Durham, NC

Abstract: Subthalamic deep brain stimulation (DBS) is an established therapy for advanced Parkinson's disease. However, the underlying mechanisms of action and brain regions directly modulated by the stimulation are not well understood. Multiple lines of evidence show that axons within the vicinity of the active electrode contact are directly activated by stimulation. Magnetic resonance imaging-based techniques, known as tractography, enable definition of the trajectories of white matter pathways within the brain on a patient-specific basis. Therefore, we developed a novel methodology that combines DBS modeling with tractography to explicitly quantify the spatial extent of axonal activation due to the DBS electric field and visualize how these activated axons pathways project to different brain regions. These tractography-activation models (TAMs) enable comparison of the different activated pathways as the stimulation parameter settings are changed in a patient. In this study, we were specifically interested in DBS of 4 pathways in the subthalamic region: 1) subthalamopallidal, 2) pallidothalamic, 3) hyperdirect, and 4) cerebellothalamic. We investigated the relative activation of these pathways during unilateral DBS in a Parkinson's disease patient that had undergone preoperative, high-field (7T) structural and diffusion-weighted magnetic resonance imaging. FSL (FMRIB, England) was used to define the pathways, the voltage distribution for the stimulation settings was calculated using finite element modeling, and the axonal response to the corresponding extracellular voltages was simulated in multi-compartment axonal models with NEURON (Yale University, USA). Our results suggest that that individual pathways can be preferentially activated by TAM-based definition of the stimulation settings in the patient. Therefore, patient-specific TAMs developed with high-field MRI data have potential to enhance our understanding of the specific pathways responsible for therapeutic benefit from DBS.

Title: Alterations of intrinsic functional connectivity in Parkinson’s disease

Authors: *T. MADHYASTHA[1], M. ASKREN[2], E. COLLINS[2], T. GRABOWSKI[2];
[1]Psychiatry and Behavioral Sci., [2]Univ. of Washington, Seattle, WA

Abstract: Correlations among low frequency spontaneous fluctuations in the blood oxygen level-dependent (BOLD) signal reflect the connectivity of intrinsic large-scale networks in the brain. Parkinson’s disease (PD) includes both motor and cognitive symptoms spanning memory and attentional domains and is characterized by systematic dopaminergic deficits. In the present study, we examine the differences between intrinsic functional connectivity in medicated early-stage PD patients (N=12, Mage=61) and healthy elderly controls (N=38, Mage=74) drawn from the Alzheimer’s Disease Neuroimaging Initiative.
We extract time-varying signals from regions of interest in attentional networks, the default mode network, and the salience network. We use a novel technique for characterizing network activity based on exploratory factor analysis of these variables in a structural equation modeling framework (ESEM) (Asparouhov & Muthén, 2009), implemented in Mplus. Within the ESEM framework the researcher can access typical SEM parameters, including standard errors, goodness of fit statistics and comparisons of competing models, and multiple group analysis. This allows rigorous comparison of the factor structure of the PD sample to that of healthy controls.
We find that the factor structure of the PD sample is significantly different than that of the

normal controls. Specifically, we observe coactivation of the anterior cingulate cortex, the posterior cingulate cortex, and right lateralized attention network nodes that is not present in controls. Differences in expression of the salience network during rest may reflect underlying dopaminergic dysfunction characteristic of PD or may be a consequence of treatments targeting the dopamine system. Dysregulation of the salience network over the course of disease may contribute to cognitive impairments observed in later stages of PD.

Title: Disruption of default mode network functional connectivity in Parkinson's disease

Authors: *M. C. CAMPBELL[1], J. M. KOLLER[2], E. R. FOSTER[3], A. Z. SNYDER[4], J. S. PERLMUTTER[1];
[1]Neurol., [2]Psychiatry, [3]Occup. Therapy, [4]Radiology, Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: Introduction: Research on resting-state functional connectivity in Parkinson disease (PD) has primarily focused on cortico-striatal motor networks; however, cortical networks are also likely disrupted in PD given the pathological markers of cortical alpha-synuclein aggregation and cognitive decline associated with PD. Based on previous studies demonstrating that the default mode network (DMN) is sensitive to neurodegenerative diseases, we hypothesize DMN functional connectivity will be disrupted in PD and relate to cognitive function.
Methods: Resting-state BOLD scans (Seimens 3T Trio) were obtained from PD participants (N =

36) while off medication and from controls (CTRL; N = 28), matched for age and head movement. Participants with excessive movement were excluded from all analyses. Seed based functional connectivity analyses focused on the DMN regions. In addition, participants completed the Clinical Dementia Rating (CDR) evaluation and neuropsychological testing to determine cognitive function. All CTRLs had normal cognition (CDR =0); there were 17 PD with normal cognition (CDR = 0) and 19 PD with cognitive impairment (CDR = 0.5). Between-group analyses of resting-state functional connectivity first compared all PD and CTRL participants and then subgroup comparisons were conducted based on CDR rating. Fisher z-transformed correlation coefficients were extracted for significant seed-cluster pairs and correlated with cognitive performance and self-reported everyday cognitive function.
Results: PD participants demonstrated significantly lower DMN functional connectivity than the CTRLs between the lateral parietal lobe and the medial prefrontal cortex (mPFC) (ps <.05). There were no significant differences in DMN functional connectivity between PD with normal cognition and those with cognitive impairment. However, there were significant linear relationships between DMN functional connectivity and overall cognitive performance, executive function, visual-spatial function, and self-reports of everyday cognitive function (ps <.05). There were no significant relationships between DMN functional connectivity and disease severity.
Conclusion: These data demonstrate that the lateral parietal lobe loses functional connectivity with the mPFC for individuals with PD regardless of cognitive status. Furthermore, loss of DMN functional connectivity was related to cognitive performance and everyday cognitive function. These results suggest that the DMN functional connectivity is sensitive to even the earliest cognitive changes associated with PD.

Title: Spectral distributions of STN local field potential in the beta band are more dynamic in movement compared to rest in subjects with Parkinson’s disease

Authors: *M. MILLER KOOP, H. BRONTE-STEWART;
Dept. of Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Local Field Potential (LFP) recordings from the subthalamic nucleus (STN) from PD subjects at rest show beta band (13-35Hz) neural oscillations and synchrony. Studies have shown that beta band synchrony is stationary at rest and is attenuated around the onset of single movements. Until recently it was not known if this attenuation continued during a longer repetitive movement. Objective: to determine whether the resting state beta rhythm was modulated with continuous repetitive movement, and if the beta rhythm during continuous movement was stationary. Methods: LFPs were recorded intra-operatively from the deep brain stimulation lead (DBS, Medtronic 3389) immediately after its placement in the STN in 13 PD subjects, off medication for over 15 hours. Task: LFPs were recorded during 30s of rest and followed by 30s of continuous repetitive wrist flexion-extension (rWFE). Hand angular velocity was collected using angular velocity sensors. Only subjects that had a beta peak at rest between 13-35Hz, and who had at least 20% attenuation in total power in the 13-35Hz band during DBS (185Hz/2.5V or 130Hz/2V) were included. Results: Mean beta band power was not different between rest and movement epochs ($p>0.05$). However visual inspection showed that in all 13 subjects, power in the beta band decreased during early periods of the task up to about 4s. Rest and movement epochs within each subject were divided up into segments: early (0-10s) and late (20-30s). The power spectral density (PSD) (frequency resolution of 1Hz) of early movement (0-10s) was compared to that of late movement (20-30s) and similarly for the early and late rest segments. The number of 1Hz frequency bins that showed a significant difference between the early and late segments were determined for rest and movement (i.e. the 95 percent confidence intervals did not overlap). The total number of 1Hz frequency bins that showed a significant change in power was more than double between the movement epochs (38) compared to the rest (18) ($p<0.01$). This indicates that although in our cohort we did not determine a significant change in the mean power in the beta band between rest and movement epochs, we did see significant changes in the spectral distributions. This finding suggests that the movement beta band is more dynamic compared to the resting beta band. Whether this dynamic process is related to the quality of the movement is yet to be determined.

Title: Sixty hertz deep brain stimulation does not attenuate subthalamic nucleus beta rhythm in parkinson's disease

Authors: H. BRONTE-STEWART[1], L. A. SHREVE[1], B. C. HILL[1], H. YU[2], J. M. HENDERSON[2], *A. VELISAR[1];
[1]Neurol., [2]Neurosurg., Stanford Univ., Stanford, CA

Abstract: Objective: Subthalamic Nucleus deep brain stimulation (STN DBS) at frequencies of 130 to 185Hz at 2V reduces tremor, rigidity and bradykinesia in Parkinson's disease (PD) and attenuates resting STN local field potential (LFP) power in the 13 - 30 Hz range (beta band). STN DBS at frequencies below 100 Hz are not therapeutic except in a few cases for freezing of gait. We hypothesized that STN DBS at a low (non-therapeutic) frequency (60Hz, 2V) would not attenuate STN DBS resting beta band power (RBP).
Methods: During the experiments patients were awake and resting on the surgical bed. LFPs were recorded from electrodes 0-2 (Medtronic 3398 lead), at rest - no stimulation (30sec), and during (20 sec) randomly presented epochs of STN DBS through electrode 1, at 130Hz/2V (therapeutic), 130Hz/1.35V and 60Hz/2V, intra-operatively in 18 PD sides off medication, immediately after DBS lead placement and clinical testing. Beta band power was calculated between 13-30Hz using previously published methods.
Results: Recordings from five sides were discarded: two due to presence of artifacts, three due to different stimulation parameters. There was significant attenuation of RBP during therapeutic DBS ($P<0.01$) and during DBS at 130 Hz/1.35V ($P <0.025$) but not during 60Hz/2V DBS. The reduction in RBP was significantly greater at 130 Hz/2V compared to that at 60 Hz/2V ($P<0.01$). Although DBS at 60Hz/2V and 130 Hz/1.35V delivered the same total energy, only 130Hz/1.35V attenuated RBP. In 4 sides STN DBS at 60Hz/2V increased RBP. Conclusions: This is the first report of the effect of clinically determined non-therapeutic frequencies of DBS on RBP in the STN and demonstrates that low frequency (60Hz) does not change and in some cases increases RBP in PD. This may support the hypothesis that a mechanism of therapeutic DBS for PD is to attenuate beta band synchrony in sensorimotor networks.

Title: Full-length proteoforms of α-synuclein from human brain tissue by top-down mass spectrometry

Authors: *J. B. WATSON[1], T. A. SARAFIAN[1], C. M. RYAN[1], P. SOUDA[1], E. MASLIAH[4], U. K. KAR[1], H. V. VINTERS[2], G. W. MATHERN[3], K. F. FAULL[1], J. P. WHITELEGGE[1]; [1]Dept Psychiatry & Biobehav Sci., [2]Dept Pathology and Lab. Med., [3]Dept Neurosurg., David Geffen Sch. Med. UCLA, Los Angeles, CA; [4]Dept. of Neurosci. and Pathology, UCSD, La Jolla, CA

Abstract: The primary amino acid structure of full-length human α-synuclein in human brain surgically removed from a young patient (5.8 years old, female, ILAE Cortical Dysplasia I) was previously determined by combined liquid chromatography and top-down mass spectrometry [Sarafian TA, Ryan CM, Souda P, Masliah E, Kar UK, et al. (2013) Impairment of Mitochondria

in Adult Mouse Brain Overexpressing Predominantly Full-Length, N-Terminally Acetylated Human α-Synuclein. PLoS ONE 8(5): e63557. doi:10.1371/journal.pone.0063557]. N-terminal acetylation of α-synuclein was the only posttranslational modification (PTM) detected in protein from this tissue. The same isoform was also the only PTM detected in protein from brain mitochondria and cytosolic fractions from an overexpressing (ASOTg) early mouse model for Parkinson's Disease (PD), save for minor C-terminal truncations. An overexpressed full-length, N-terminally acetylated mostly monomeric form of human α-synuclein was sufficient to disrupt adult brain mitochondrial function in the ASOTg mice. Thus α-synuclein PTMs appear to occur infrequently in young human brain but may increase progressively with age in PD brain. New top-down mass spectrometric approaches are now in progress to examine the major proteoforms of α-synuclein in greater detail, and in additional resected brain samples, as well as in postmortem midbrain tissue from older PD, Diffuse Lewy Body Disease (DLBD), and DLBD plus Alzheimer's disease (AD) cases.

Title: Human embryonic dopamine neurons transplanted into putamen of Parkinson patients survive for at least 22 years without immunosuppression

Authors: *C. R. FREED[1], R. E. BREEZE[2], W. M. ZAWADA[1], S. FAHN[3], D. EIDELBERG[4], S. JONES[1], W. ZHOU[1];

Abstract:
We have shown that embryonic dopamine cell transplants significantly improve objective signs of Parkinson's disease in direct relation to the preoperative response to L-dopa. We have now studied postmortem brain of 12 subjects who have died 7 months to 22 years after transplant.

Dopamine neurons were identified immunohistochemically in transplant tracks using a primary antibody to tyrosine hydroxylase and a secondary antibody labeled with fluorescent FITC. After identification of dopamine neurons by green fluorescence, pigment density was determined by measuring white light transmission through the cytoplasm of each cell. Twenty-five cells in each transplant track were measured. Pigment density increased linearly in transplanted dopamine neurons during the years after transplant. Parallel studies were performed on substantia nigra of children and adults who did not have Parkinson's disease. A similar age-related accumulation of pigment was seen. Despite the absence of immunosuppression at the time of surgery and in subsequent years, every transplanted fragment of human embryonic mesencephalon showed surviving dopamine neurons, indicating that the immune system did not destroy any transplant. While a few isolated Lewy-body like inclusions were occasionally observed, all transplants showed extensive fiber outgrowth into putamen, demonstrating that the transplanted dopamine neurons were physiologically robust. The total number of surviving dopamine neurons in each transplant site was not related to the years since transplant, showing that there was no progressive loss of neurons with time. The largest number of surviving dopamine neurons was found in a patient who died at age 85, ten years after transplant; therefore, patient age does not adversely affect survival of dopamine neurons.. We conclude that transplanted human dopamine neurons undergo morphologic evolution essentially identical to that seen in the normal substantia nigra. Our results indicate that the neurotrophic environment of the putamen of patients with idiopathic Parkinson's disease is normal since it can support long term development of transplanted dopamine neurons.

Title: Correlation between altered cerebrospinal fluid levels of α-Synuclein and Aβ1-42 in Parkinson disease

Authors: *C. BUDDHALA, M. CAMPBELL, J. S. PERLMUTTER, P. T. KOTZBAUER; Neurol., Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: Accumulation of misfolded α-synuclein (α-syn) protein in Lewy bodies and Lewy neurites is the defining pathologic feature of Parkinson disease (PD). The development of dementia in PD is consistently associated with neocortical α-syn accumulation. In our previous autopsy study, 60% of PD patients with dementia had neocortical accumulation of Aβ plaques. We investigated the metabolism of α-syn and Aβ1-42 in cerebrospinal fluid (CSF) to determine their utility as biomarkers for diagnosis and disease progression in PD. We measured baseline CSF levels of α-syn, Aβ1-42, total tau and phosphorylated tau in a cross-sectional cohort comprising idiopathic PD participants (n=60) and age-matched controls (n=20). CSF levels of α-syn and Aβ1-42 were significantly lower in PD (α-syn; p=0.0008, Aβ; p=0.0067) when compared to controls, but differences in CSF total tau and phosphorylated tau were minimal. In addition, when PD participants were stratified on the basis of clinical dementia rating (CDR) scale scores, the levels of CSF Aβ1-42 were lower in PD with mild cognitive impairment (CDR=0.5; n=23) (p=0.047) when compared to those without cognitive impairment (CDR=0; n=30). Moreover, CSF Aβ1-42 levels correlated inversely with mean cortical binding potential, as assessed by [C-11] - labeled Pittsburgh compound B amyloid imaging scans. There was also a strong positive correlation between CSF levels of α-syn and Aβ1-42 in PD participants ($p<0.001$) but not in controls, further supporting a connection between altered α-syn and Aβ metabolism in PD.

Title: The effect of subthalamic nucleus deep brain stimulation on effective connectivity within the basal ganglia motor loop

Authors: *J. KAHAN[1], M. URNER[2], A. MARREIROS[1], R. MORAN[3], L. ZRINZO[1], M. HARIZ[1], P. LIMOUSIN[1], K. FRISTON[4], T. FOLTYNIE[1];

Abstract: Starved of dopamine, the dynamics of the Parkinsonian brain result in a combination of symptoms impacting on both 'action' and 'resting' motor behaviour. Deep brain stimulation (DBS) has become an established means of managing these symptoms, although its mechanisms of action remain unclear. Dynamic causal modelling (DCM) of neuroimaging data can provide estimates of effective connectivity within and between regions of a network, furnishing predictions about how the observed neuroimaging data might have been generated. Original implementations of DCM regard the brain as a nonlinear deterministic system, requiring the experimenter to 'perturb' the system with exogenous inputs (experimental stimuli) in order to infer task-related effective connectivity. A recent extension ('stochastic DCM') incorporates random fluctuations into the equations governing the neuronal evolution of each region, freeing the system from deterministic assumptions, allowing the experimenter to model directed connectivity in the resting brain. In this work, we model the effective connectivity within the resting motor loop of the human brain in 12 patients with Parkinson's disease, with and without active bilateral subthalamic nucleus (STN) DBS, using resting state functional magnetic resonance imaging. Utilising a well-established, simplified model of the functional architecture of the motor cortico-striato-thalamic loop, we probe which connections, or combinations of connections are modulated by STN DBS to produce the observed BOLD signal recorded at rest. Using Bayesian model selection, we are able to demonstrate that a model incorporating DBS-related modulatory effects on the extrinsic direct, indirect, hyperdirect, thalamo-cortical, as well as cortico-striatal pathways, consistently outperforms equally plausible hypothesised models (posterior probability > 99%). Post-hoc model family analysis reiterates this further (posterior probability > 99%). Our findings highlight the disseminated effects of deep brain stimulation of the Parkinsonian resting motor network, specifically on the coupling between the cortex and basal ganglia, as well as between the nuclei of the basal ganglia. This work is an example of how researchers can use this method to provide a mechanistic insight into neurological/psychiatric diseases and their therapies in a non-invasive manner, without requiring the subject to complete a mentally demanding task. This work also provides a framework for analysing effective connectivity in resting state fMRI data with strong a priori hypotheses.

Title: Application of temporally non-regular deep brain stimulation to a control theory model of the parkinsonian basal ganglia

Authors: *C. M. DAVIDSON[1], A. M. DE PAOR[1], M. M. LOWERY[2];
[1]Sch. of Electrical, Electronic and Communication Engin., Rm. 149, Belfield, Ireland; [2]Sch. of Electrical, Electronic and Communication Engin., Rm. 152, Belfield, Ireland

Abstract: Deep Brain Stimulation (DBS) applied to either the subthalamic nucleus (STN) or the globus pallidus pars interna (GPi) effectively alleviates the motor symptoms of advanced Parkinson's disease that are no longer controllable with drug therapy alone. In Parkinson's disease dopamine loss leads to an increase in both the functional connectivity and oscillatory activity within the basal ganglia. Correlation between this oscillatory activity in the beta band (12-35Hz) and the motor symptoms of the disease has been established. Suppression of these oscillations by either drug therapy, DBS or a combination of both also correlates with an improvement in the motor symptoms of the disease. In current clinical practice, DBS consists of a regular, biphasic pulse train applied at frequencies in the 130-185Hz range, with the amplitude, pulse duration and frequency of stimulation adjusted for optimal patient improvement. In this study a computational mean-field model, which aims to capture the key physiological mechanisms of a group of interacting neurons in a mathematically tractable way, is used to represent the Parkinsonian basal ganglia. The effect of applying temporally non-regular stimulation to beta oscillations simulated using the computational model is examined. A number of different stimulation patterns are applied and the efficacy of each compared. Although they are specific to the model used, the results suggest that non-regular stimulation may provide greater suppression of oscillations than that achieved with regular stimulation, and therefore equivalent improvement in the motor symptoms would be predicted.

Title: The evolution of lead fixation techniques in deep brain surgery

Authors: *B. BROWN, C. VAN HORNE;
Dept. of Neurosurg., Univ. of Kentucky, Lexington, KY

Abstract: Deep brain stimulation (DBS) has demonstrated effective symptom relief for Parkinson's disease, essential tremor, dystonia, and may be an emerging treatment approach for Alzheimer's disease, depression, and obsessive-compulsive disorders. However, as with all device related procedures, complications are unavoidable. There are numerous reports in the literature regarding complications from DBS; however, there are few regarding complication prevention. In this study, the authors performed a review of published techniques for lead fixation as well as to present their anchoring technique. The novel lead fixation technique utilizes a silastic tubing to protect the lead, an injectable calcium phosphate cement (HydroSet®), and a titanium craniofacial miniplate. The HydroSet® sets rapidly, is non-toxic, is non-exothermic (as compared to methyl methacrylate), and stabilizes the lead prior to final fixation to the skull with the miniplate. The described technique has been utilized in 44 patients for implanted electrodes in the subthalmic nucleus, thalamus, or globus pallidus for a total of 66 lead placements without incidence of lead damage, migration, or infection.

Title: Optimized temporal patterns of deep brain stimulation reduce parkinsonian symptoms at low frequencies

Authors: *D. T. BROCKER[1], B. D. SWAN[1], R. Q. SO[1], D. A. TURNER[2], R. E. GROSS[4], W. M. GRILL[3];

Abstract: Deep brain stimulation (DBS) was developed empirically to use short (60-180 μs), high frequency (>100 Hz) pulses of electrical stimulation to ameliorate the motor symptoms of Parkinson's disease (PD). Current DBS systems deliver a regular pattern of stimulation (i.e., interpulse intervals do not vary across time), but the efficacy of DBS depends on the temporal pattern of stimulation, with random patterns of DBS exhibiting decreased efficacy, and some specific patterns exhibiting increased efficacy. We sought to exploit the dependence on temporal pattern and used model-based optimization to design a non-regular pattern of DBS for PD and subsequently tested this pattern in a hemi-parkinsonian rat model of PD and in human subjects with PD. We coupled a computational model of the PD basal ganglia with an engineering optimization technique (genetic algorithm) and designed a non-regular pattern of stimulation with a low average frequency of stimulation (45 Hz) and efficacy in the computational model similar to high frequency regular stimulation.

In hemi-parkinsonian rats and human subjects with PD, the optimized non-regular pattern of DBS was compared to high frequency regular stimulation, frequency-matched regular stimulation, and the stimulation-off condition. Performance was evaluated in the hemi-parkinsonian rats using two established methods for evaluating parkinsonian symptoms: methamphetamine-induced circling test and the bar test of akinesia. The optimized non-regular pattern of stimulation reduced parkinsonian motor symptoms in the rats more effectively than the stimulation off condition and frequency-matched regular stimulation. Bradykinesia and parkinsonian tremor were evaluated in human subjects with PD using an alternating finger tapping task and an accelerometer taped to the dorsum of the subjects hand, respectively. Again, the optimized non-regular pattern of stimulation reduced parkinsonian motor symptoms in the human subject more effectively than the stimulation off condition and frequency-matched regular stimulation. Finger tapping task performance was similar between the optimized 45 Hz pattern of stimulation and 185 Hz high frequency stimulation.

These results reinforce that temporal pattern is an important DBS parameter and provide evidence that non-regular patterns may be used to increase the efficiency of DBS for PD. The low average frequency of the optimized pattern of stimulation may reduce both stimulation-induced side effects and power consumption, thereby lengthening battery life and time between implantable pulse generator replacement surgeries.

Title: Mobility in Parkinson's disease is improved through classical ballet-based instruction

Authors: *M. V. ALBERT, W. GOMEZ, A. MISKOVICK, C. LOPEZ-ORTIZ;
Rehab. Inst. of Chicago, Northwestern Univ., Chicago, IL

Abstract: Evidence is presented which indicates that classical ballet instruction, an enjoyable group activity, can improve motor symptoms in people with Parkinson's disease (PD). PD affects over four million adults throughout the world. Individuals with PD suffer from a number of impairments in movement and posture including tremor, rigidity, bradykinesia (slow movement), poor balance, and impaired gait. Exercise therapies have demonstrated significant improvements in PD symptoms, with dance classes increasingly being considered as a more enjoyable variant of exercise therapy. We present a pilot study of a classical ballet-based intervention involving five participants with PD. Uniquely to the design of this classical ballet PD class, each exercise was selected or adapted to counter a specific mobility deficit in Parkinson's disease; exercises emphasized mobility of each joint proximally to distally, coordination of lower and upper limbs as needed for a normal gait cycle, functional reaching, rhythmicity and phrasing in movement, and inclusion of principles from LSVT BIG therapy, all within the context of classical ballet technique. Subjects participated in a one-hour class twice per week over a period of eight months with a minimum attendance rate of 75%. Our mobility measures were the 10 meter walk test, the five times sit to stand test, the 360 degree turn test, and the composite Timed Up and Go (TUG) test calculated from the previous measures. All tests were performed at the beginning of the first and last class. Significant differences were found in the 10m walk test ($p<0.005$, paired t-test), the five times sit to stand test ($p<0.016$) and the composite TUG test ($p<0.004$). The timed 360 degree turn test demonstrated a decrease that was not statistically significant ($p >0.229$). To our knowledge, this pilot study is the first to report significant improvements in motor scores in a classical ballet-based dance class for subjects with PD.

Title: Effects of istradefylline alone and in combination with levodopa on motor and cognitive function in the MPTP-treated macaque model of Parkinson disease

Authors: *E. Y. PIOLI[1], Q. LI[1], J. YANG[1], A. CROSSMAN[1], E. BEZARD[2], J. S. SCHNEIDER[3];
[1]MOTAC, Manchester, United Kingdom; [2]Inst. of Neurodegenerative Dis., Bordeaux, France; [3]Thomas Jefferson Univ., Philadelphia, PA

Abstract: Istradefylline has been suggested as an adjunct to L-dopa to decrease OFF time and to improve the ON period functioning in advanced Parkinson's disease (PD) patients experiencing L-dopa-related treatment complications. Little is known however about the effects of this drug, alone or in combination with L-dopa, on motor or cognitive symptoms in mild/moderate PD. Thus, the current was performed to evaluate effects of the adenosine A2A antagonist istradefylline, alone and as an adjunct to levodopa (L-dopa), on motor symptoms and cognitive functioning in a nonhuman primate Parkinson model. Six adult male cynomolgus macaque monkeys, previously trained to perform cognitive tasks (working memory, attention) were chronically administered MPTP until cognitive deficits appeared. After cognitive deficits were documented, MPTP administration continued with increasing doses until mild/moderate Parkinsonian motor symptoms emerged. Istradefylline was administered at 60, 75, and 100 mg/kg and motor and cognitive function were tested 50 min. later. L-dopa was administered at 2.5 - 25 mg/kg and was tested for effects on motor and cognitive functioning alone and in combination with istradefylline. Low doses of L-dopa partially improved motor symptoms and higher doses maximally improved motor symptoms. Istradefylline alone had no effect on motor symptoms and provided no additional benefit when added to either low or high doses of L-dopa. At low doses, istradefylline had no positive effect on working memory or attention and at higher doses tended to further disrupt at least some cognitive functions. In some animals, high dose L-dopa decreased commission errors on the attention test but at the expense of increasing omission errors. Istradefylline alone had no effect on attention. Addition of istradefylline to either low or high doses of L-dopa provided no benefit. Istradefylline shows little ability to improve motor or cognitive function, either alone or in combination with L-dopa, in a mild/moderate PD model that expresses both cognitive and motor deficits

Title: Positive signals from biomarkers predict YKP10461 will be effective in Parkinson's disease

Authors: *D. P. TAYLOR, E. GRAHAM, A. PEGAN, H. W. KIM, W. HAN;
SK Life Sci., FAIR LAWN, NJ

Abstract: Type B monoamine oxidase (MAO_B) preferentially metabolizes phenylethylamine (PEA) and dopamine. The activity of MAO in human thrombocytes is almost exclusively type B and reflects brain MAO_B activity. MAO_B has been identified in human brain tissue with its activity increasing with age, and it has been studied widely in neuropsychiatric disorders. The inhibition of this enzyme is one of the important therapeutic strategies for the treatment of Parkinson's disease and other neurodegenerative diseases. MAO_A preferentially deaminates norepinephrine (NE) and serotonin. Dihydroxyphenylglycol (DHPG) is the metabolite of NE formed by this isozyme. Foods high in tyramine ingested along with a MAO_A inhibitor are known to increase blood pressure, sometimes to a dangerous degree, by displacing NE from intraneuronal stores. YKP10461 is a new chemical entity selected for the study of its potential in the treatment of PD because of its potent, selective, and reversible inhibition of MAO_B. (Park *et al*., 755.29. *Soc for Neurosci* 2012).
In the course of a Phase 1 first in human, single ascending dose study for safety and tolerance, pharmacokinetic (PK) parameters were obtained (Ciric *et al*., AAPS abstracts, 2013, in press). In this clinical study, 60 healthy subjects were enrolled at a single center: 10 subjects in each of 6 sequential cohorts. In each cohort, 7 subjects received oral doses of YKP10461 and 3 subjects

received placebo. The doses used were 10, 25, 50, 100, 200, and 250 mg. Blood samples from this study were analyzed for the presence of YKP10461 and, additionally, for MAO_B activity and levels of PEA and DHPG to assess the potential safety and efficacy in later proof of concept trials in PD.
The PK findings indicated that YKP10461 was orally available with C_{MAX} and AUC dose-proportional over all doses. Inhibition of MAO_B occurred in all cohorts and in all subject receiving YKP10461 compared
to subjects receiving placebo. Subjects dosed with YKP10461 showed elevation of PEA in all cohorts compared to placebo subjects. Only the first cohort (10 mg) and last cohort (250 mg) were analyzed for DHPG. No difference in DHPG levels was found between the dosed and placebo groups at either dose.
The findings regarding MAO_B and PEA demonstrate proof of pharmacology and suggest that efficacy studies may target doses lower than 10 mg. The finding of no change in DHPG levels strongly suggests that no inhibition of MAO_A occurred, signifying a lack of risk for tyramine-induced hypertensive crisis. In summary, YKP10461 has been confirmed in humans to be a potent and selective MAO_B inhibitor with potential efficacy and safety in the treatment of PD.

Title: Peripheral nerve graft implants into the substantia nigra of subjects with Parkinson’s disease undergoing deep brain stimulation surgery: A safety study

Authors: *J. E. QUINTERO[1], W. S. Z. ASFAHANI[2], F. ZAHEER[3], J. A. GURWELL[3], G. A. GERHARDT[4], J. T. SLEVIN[3], C. G. VAN HORNE[2];

[1]Univ. Kentucky, Lexington, KY; [2]Neurosurg., [3]Neurol., [4]Anat. & Neurobio., Univ. of Kentucky, Lexington, KY

Abstract: In Parkinson's disease (PD), the substantia nigra undergoes a loss of dopaminergic cells and cell function that, in part, manifests into the outward symptoms of PD. One avenue of intense efforts to treat this disease involves the delivery of neurotrophic factors to restore cell function. Previous studies have shown that neurotrophic factors including GDNF, BDNF, and NT-3 can promote dopaminergic function. Continuous, targeted delivery of these growth factors to patients, however, has been fraught with complications and failures. An alternative source of neurotrophic factors may be Schwann cells from the peripheral nervous system. After injury, Schwann cells release a host of growth factors including GDNF, NGF, BDNF, and NT-3. We have begun a pilot study to examine the safety and feasibility of implanting an autologous peripheral nerve graft into the substantia nigra of PD patients undergoing deep brain stimulation (DBS) surgery. Multi-stage, DBS surgery targeting the subthalamic nucleus is performed using standard procedures. After the DBS leads are implanted, a section of sural nerve (approximately 5mm in length) containing Schwann cells is excised and unilaterally delivered, using a custom-designed cannula, into the area of the substantia nigra. While immediate post-operative magnetic resonance scans do not indicate evidence of tissue disruption, MR-images will be further examined at three and 12 months after surgery. Meanwhile, adverse events are being continuously monitored. Neuropsychological assessments conducted 12 months after the implant surgery will be compared to pre-surgery assessments. Subjects will undergo a unified Parkinson's disease rating scale (UPDRS) evaluation before surgery and at 1, 3, 6, 9, and 12 months after surgery. On-going evaluations will help assess the safety and feasibility of implanting peripheral nerve tissue in conjunction with DBS implant surgery for patients with PD.

Title: Impedance reliability across neuromodulation devices during neurostimulator replacement

Authors: *E. L. HARGREAVES[1], R. J. DITOTA[1], S. WONG[2], S. F. DANISH[1]; [1]Neurosurg., [2]Neurol., Robert Wood Johnson Med. Sch., New Brunswick, NJ

Abstract: Deep Brain Stimulation (DBS) is an established adjunct neurosurgical treatment for movement disorders. At the heart of the DBS system is the neuromodulation device, which has a number of diagnostic capabilities to ensure the integrity of the DBS system. One of these capabilities is impedance testing. We have shown previously that Medtronic's most recent Activa (PC/SC) neurostimulators are more accurate in identifying the impedance of known resistors during bench tests than their Soletra predecessors. Further we have shown that the accuracy of all devices declines as the battery charge wears down, particularly for resistances outside the clinical range. Regardless, Soletras and the models from the Activa family within the clinical range of 1000 Ohms are typically accurate to within 5%, which can increase to 10% as the battery declines. All neurostimulator models at this impedance tend to overestimate the impedance. Here, we compare the impedance assessments of Soletras about to be deactivated to the impedance assessments of their newly implanted replacement Activa SCs. The Soletras were replaced in pairs, and as such, a number of the devices were considered functioning at a normal battery charge, with only their contralateral counterparts failing. Thus, the discrepancy between the device impedance assessments was examined. Nine individuals predominantly implanted in the subthalamic nucleus (STN), but also one in the ventral intermediate nucleus of the thalamus (VIM), and one in the globus pallidus interna (GPi), underwent replacement of 18 devices, of which 16 had sufficient charge to perform impedance assessments. Consistent with our previous bench tests, the results indicate that the Activa SCs systematically estimated the impedance to be 7% lower than that estimated by the Soletras (a mean difference of 63 Ohms; sem 20.73). If the differences between the Soletras and Activa SCs were grouped according to the battery charge of the Soletras to be replaced (failing <3.67V vs. functioning >3.69V) then these differences diminished from 8.7% to 4.9% respectively. Further, battery charge correlated positively with the difference in the failing Soletra grouping (r=.49), while battery charge was uncorrelated in the functioning Soletra grouping (r=.08). We interpret this to suggest that the spread of Battery charges and impedance differences were diminished in the functioning Soletra group, just as the spread was exaccerbated in the failing Soletra group. Finally, these reported differences exceed those recorded from simple same device (Activa PC) transient deactivations.

Title: Monitoring the effects of subthalamic nucleus deep brain stimulation on sensorimotor cortex and peripheral muscles

Authors: *J. P. MENON[1], M. MIYAKOSHI[2], S. LESSIG[3], S. MAKEIG[2], D. BARBA[1]; [1]Univ. of California, San Diego Neurosurg., San Diego, CA; [2]Univ. of California, San Diego Swartz Ctr. for Computat. Neurosci., San Diego, CA; [3]Univ. of California, San Diego Neurosci., San Diego, CA

Abstract: Background
Deep brain stimulation (DBS) has been used for controlling motor symptoms of Parkinson's disease. Optimizing the DBS parameters using objective measures is desirable. Here we report the first result of mobile brain/body imaging using simultaneous high-density scalp EEG, neck and arm EMG, and body motion capture recordings from Parkinson's disease patients at onsets and offsets of bilateral subthalamic nucleus deep brain stimulation to observe resulting tremor modulation.
Materials and Methods
Parkinson's disease patients with DBS treatment (n = 3) underwent EEG recording sessions. Here we report results on one subject. EEG was recorded from 192 electrodes placed on the scalp. Electromyographic (EMG) activity was recorded from 64 surface electrodes places on the right arm surface. The subject was seated comfortably. During recording, the experimenter switched the subject's DBS unit on or off at 1-minute intervals in a 108-minute session. EEG data were analyzed using EEGLAB (sccn.ucsd.edu/eeglab). Data were low-pass filtered below 50 Hz, and were linearly decomposed using adaptive mixture independent component analysis (AMICA) to obtain time-domain independent component activities, which were converted into the time/frequency domain using a wavelet transform. Equivalent dipole models were computed for stationary scalp topographies of independent component processes originating in brain source activity.
Results
Event-related potential (ERP) analysis revealed that turning on the DBS unit produced significant EEG power suppression in the beta band (15-30 Hz) activity in bilateral sensorimotor cortices about 4-sec after DBS onset. Importantly, DBS onset was also associated with strong attenuation of EMG power near 5 Hz and its harmonics in right neck muscle source activities and right arm EMG channels. Simultaneous motion-capture data from right arm markers also showed a near 5-Hz peak.
Conclusions
This result demonstrates that DBS suppresses beta-band activity in sensorimotor cortex, as well as suppressing tremor-associated EMG activity, and establishes the feasibility of using mobile brain/body imaging (MoBI) methods to monitor modulation of brain activity associated with movement disorders.

Title: Subthalamic nucleus stimulation induces cortical and corticospinal plasticity in Parkinson's disease

Authors: *D. WEISS[1], R. KLOTZ[2], R. GOVINDAN[3], M. SCHOLTEN[1], C. PLEWNIA[4], F. BUNJES[1], A. GHARABAGHI[5], R. KRÜGER[1];

Abstract: Introduction
Pathological motor processing of the subthalamo-thalamo-cortico-spinal long-range motor network is under investigation as a mechanism to explain therapeutic effects of subthalamic neuromodulation therapy in Parkinson's disease. Here, we aimed to address the modulatory effect of subthalamic nucleus deep brain stimulation (STN-DBS) on cortical activity and corticospinal long-range motor network processing.
Methods
Twenty iPD patients with STN-DBS both OFF [StimOff] and ON [StimOn] underwent externally cued finger taps simultaneous to combined EMG (flexor digitorum, FD & extensor digitorum, ED muscles) and 64-channel EEG recordings. EEG data were LaPlace transformed as spatial filter. Time-frequency decompositions of local cortical and muscular activity and long-range synchronisation (coherence) between cortex and antagonistic muscles were performed using Morlet wavelets (EEGlab / Fieldtrip). Permutation statistics using a cluster-based correction method were subsequently performed on event-related spectral pertubations to compare between treatment conditions on group-level ([StimOff] vs. [StimOn]).
Results
Significant modulations of the cortical event-related desychronisation (ERD) and of event-related corticospinal synchrony were detected: ERD in the alpha and beta bands (8-30Hz)

presented over a broad cortical area including the bilateral SM1, supplemental motor and frontal areas and was significantly facilitated with [StimOn] compared to [StimOff]. Whereas corticomuscular coherence with both FD and ED was observed mainly in the pre-movement phase similarly with both [StimOff] and [StimOn], an 'abnormal' premature rebound of beta band corticomuscular coherence with ED was observed in the [StimOff] condition (pronounced at left SM1 region).
Conclusions
Our findings demonstrate that the significant therapeutic effects of STN-DBS are paralleled by significant modulations of both cortical and corticospinal long-range motor processing.

Title: Subthalamic deep brain stimulation synchronizes cortical activity in humans with Parkinson's disease: Intraoperative investigation of single unit discharges and scalp potentials

Authors: *H. C. WALKER, C. L. GONZALEZ, H. HUANG, B. L. GUTHRIE;
Neurol., UAB, Birmingham, AL

Abstract: Introduction: Subthalamic deep brain stimulation is more effective than medications for motor symptoms of Parkinson's disease, and recent evidence suggests that alteration of activity within the cortico-subthalamic or "hyperdirect" pathway may relate to its therapeutic mechanism. Little is known about potential interactions between cerebral cortex and single unit subthalamic discharges in behaving humans with Parkinson's disease.
Methods: With prior IRB approval, we evaluated 9 subthalamic units from 4 participants with advanced Parkinson's disease who underwent surgery for routine clinical care, simultaneously performing microelectrode recordings and non-invasive scalp electroencephalography during

DBS electrode placement. We identified movement-responsive subthalamic units and compared their discharge patterns with rasters and histograms during passive versus self-paced voluntary movements of the contralateral hand. Additionally, we calculated spike-triggered averages of scalp potentials and event related potentials to the stimulus from the DBS electrode at different depths along the recording trajectory.
Results: Passive and active joint manipulation were both associated with alterations in subthalamic single unit discharge patterns. Among the units, 6/9 (67%) responded to passive finger movements, and 5/9 (56%) responded to active movements. Event related potentials to the stimulus pulse at the same location were reliably associated with polyphasic, short latency responses at the scalp with initial peak latencies as early as approximately one millisecond after the stimulus pulse. Ongoing analyses are evaluating single unit subthalamic discharges and scalp potentials and their relationship to the timing of contralateral active and passive hand movements.
Conclusions: Single unit subthalamic discharges in humans with Parkinson's disease respond readily to both passive and active contralateral hand movements, and DBS at the same site yields short latency, polyphasic ERPs that can measured non-invasively from scalp electrodes. Better characterizing the functional connectivity of the cortico-subthalamic projection has the potential to improve our understanding of the systems physiology of DBS and the pathophysiology of basal ganglia disorders.

Title: The effect of magnetic resonance imaging (mri) sequences on the settings and impedances of the activa pc/sc

Authors: *R. P. PATEL[1], C. S. OZA[2], S. F. DANISH[1], E. L. HARGREAVES[1];
[1]Div. of Neurosurg., Robert Wood Johnson Med. Sch., New Brunswick, NJ; [2]Biomed. Engin., Drexel Univ., Philadelphia, PA

Abstract: Deep Brain Stimulation (DBS) is an established adjunct neurosurgical treatment for movement disorders. Stimulating leads are stereotactically implanted in different targets

according to movement disorder and symptoms. Neuromodulation devices are attached to the leads and implanted subcutaneously inferior to the clavicle. Although coiled and made of a non-ferrous 80/20 platinum /iridium mix, the leads and device limit the postoperative magnetic resonance imaging (MRI) opportunities of those implanted.
Regardless, MRI during the immediate postoperative period can assist in determining proper stimulating lead placement, and detecting adverse events related to the surgery. MRI during the long term can detect lead shift, and other burgeoning brain abnormalities that may impact overall health. Thus, MRI safety is essential for effective DBS therapy management. Large MRI series have been reported for previous neuromodulation devices, but no data have been presented concerning the impact of MRI on the Activa family of devices.
Eighteen patients implanted with 21 Activa family devices (15 with 1 PC, 2 with 2 SCs, and 1 with 2 PCs) were examined during postoperative MRI sequences (ranging from a week to years post-implantation). Nine individuals underwent sequences developed in 2003 and retrospectively were determined to exceed current head coil Specific Absorption Rate (SAR) levels. The subsequent nine individuals underwent sequences that were adjusted to be more in line with the recommended SAR levels. The new SAR levels were two thirds to half those of the earlier sequences. Additionally, data were obtained from eight individuals, who underwent simple deactivations paralleling the time devices would be in the off state to undergo MRI sequences. The device activation state, the stimulation parameter set, and the monopolar and a subset of the bipolar impedances were examined.
Results indicate that neither activation state, nor stimulation parameters were altered, as a consequence of the MRI sequences, counter to what has been reported for earlier devices. Additionally, a small (<1%), but statistically significant increase in impedances was detected as a result of the MRI sequences, none of which were symptomatic. The MRI group with lessened SAR levels had less of an impedance increase then the MRI group undergoing the scans at the original SAR levels. Additionally, those with lessened SAR levels did not have impedance increases that were different than those individuals undergoing simple deactivations. Further analyses relating the impedance changes to time after implantation, baseline impedance levels, and total electrical energy delivered are underway.

Title: Impedance variability of the activa PC/SC across intervals of days to months during which the stimulating parameters are held constant

Authors: *N. V. PATEL[1], D. L. CAPUTO[2], R. J. DIPAOLA[2], D. MCMULLEN[1], S. F. DANISH[1], E. L. HARGREAVES[1];
[1]Div. of Neurosurg., [2]Neurol., Robert Wood Johnson Med. Sch., New Brunswick, NJ

Abstract: Deep Brain Stimulation (DBS) is an established adjunct neurosurgical treatment for movement disorders. At the heart of the DBS system is the neuromodulation device, which has a number of diagnostic capabilities to ensure the integrity of the DBS system. One of these capabilities is impedance testing. We have shown previously that Medtronic's most recent Activa family (PC/SC) of neuromodulation devices are more accurate in identifying the impedance of known resistors during bench tests than their Soletra Kinetra predecessors. Recently Cheung et al., (2013) reported a number of Soletra impedance variance sources during the course of DBS therapy, including time. These sources were derived as the stimulation parameters were altered to maintain therapeutic benefit. Earlier, Sillay et al., (2010) also examined Soletra impedance variance, but did so across intervals in which the stimulating parameters were held constant, reporting no systematic change over time. Here, we replicate the Sillay et al., study for the newer Activa PC/SC neurostimulator models.
Monopolar impedances were drawn from 17 individuals at various stages of their DBS therapy (16 with single PCs, 1 with dual SCs). In total, data were collected from 32 stimulating leads, averaged across all 4 contacts. Inclusion Criteria for the impedance assessments were that the stimulating parameters be monitored for three standard therapeutic programming sessions, with the first, setting the parameters, the second keeping the parameters the same, and the third assessing the impedances prior to any programming changes. Thus, the stimulating parameters would be identical between the second and third sessions, with the impedances between these latter two sessions being of interest. The same setting interval had a mean of 64 days (3-147), while the post implantation interval had a mean of 588 days (92 to 1688). Settings were also converted to a Total Electrical Energy Delivered (TEED) measure. Results confirmed those of Sillay et al. (2010), in that there was no systematic change in impedance across the interval of same settings. The mean difference of 17.2Ohms was near identical to that of Sillay et al., although the variance was less. Unlike Sillay et al., significant relationships were found between the impedance difference and 1) the interval of same settings, as a proportion of the time from implantation (r=.37), 2) the same setting interval proportion multiplied by the TEED for the same duration (r=.50). A strong correlation between TEED and post implantation interval was also found (r=.78).

Title: Intensity-dependent modulation of motor skill acquisition in Parkinson's disease by transcranial direct current stimulation

Authors: *B. J. POSTON[1], R. R. WALSH[1], E. L. HEISLER[1], J. L. ALBERTS[2];
[1]Biomed. Engin., Cleveland Clin. Lou Ruvo Ctr. For Brain Hlth., Las Vegas, NV; [2]Biomed. Engin., Cleveland Clin. Fndn., Cleveland, OH

Abstract: Transcranial direct current stimulation (tDCS) is a non-invasive brain stimulation method that has recently shown promise as a modality to increase motor function in Parkinson's disease (PD). However, the optimal stimulation parameters for impacting motor function through tDCS have not been established. The purpose was to determine the influence of the intensity of tDCS on motor skill acquisition in PD. The study was a sham-controlled, cross-over experimental design and 6 subjects diagnosed with idiopathic PD participated in the study. Subjects completed 3 experiments each separated by a 7 day washout period. Each experiment involved practice of a precision grip task (primary practice task; PPT) performed in association with 1 of 3 tDCS interventions (1 mA, 2 mA, and SHAM) in counterbalanced order. The PPT involved matching a target sine wave (0.5 Hz; target force range: 5-25% of maximum) for 10 trials that each involved matching the template for 30 s followed by a 90 s rest (total time = 20 min) while under stimulation. tDCS was applied to the scalp area overlying the hand area of the contralateral motor cortex of the primarily affected hand. SHAM stimulation was applied in the same experimental settings and according to a well-established protocol that elicits the same sensations on the surface of the scalp as application of real tDCS. Force error was quantified as the average error in force relative to the target force in the PPT. tDCS applied at 2 mA lead to better performance (12.5% lower force error) compared to SHAM stimulation. However, there was no difference in force error between the SHAM and 1 mA conditions. The findings indicate that a single application of tDCS at 2mA, but not 1 mA can increase the rate of motor skill acquisition in PD patients. Thus, tDCS may represent an intervention with a realistic potential to be translated into clinical practice because it is also relatively inexpensive, easy to operate, portable, and extremely safe. However, more research is needed to determine the optimal tDCS parameters to acutely increase motor function in PD and the extent to which chronic tDCS may further enhance these positive effects.

Title: Lack of effect of donepezil, a central cholinesterase inhibitor, on motor or cognitive performance in the MPTP macaque model of Parkinson's disease

Authors: *A. R. CROSSMAN[1], E. PIOLI[2], Q. LI[2], J. S. SCHNEIDER[3], E. BEZARD[4];
[1]The Univ. of Manchester, Manchester, United Kingdom; [2]Motac Neurosci., Manchester, United Kingdom; [3]Thomas Jefferson Univ., Philadelphia, PA; [4]Inst. of Neurodegenerative DIseases, Bordeaux, France

Abstract: Central cholinesterase inhibitors have been suggested for possibly alleviating motor and non-motor symptoms in Parkinson's disease (PD) as well as L-DOPA-induced dyskinesias. A thorough examination of the effects of cholinesterase inhibitors in the gold-standard experimental models of PD is, however, lacking. The purpose of the present study was to examine the effects of donepezil, a typical cholinesterase inhibitor, on motor and cognitive performance in the MPTP-lesioned macaque models of Parkinson's disease.
The doses selected for study were 80 and 160 μg/kg (i.m.) since we had previously shown these doses to be effective in improving short-term memory in aged monkeys (assessed by the delayed matching-to-sample test on the CANTAB system), a result in line with the effects of cholinesterase inhibitors in patients with mild cognitive impairment or Alzheimer's disease. In a chronic low dose MPTP macaque model of Parkinson's disease in which animals develop cognitive deficits similar to those seen in Parkinson's disease patients, donepezil had no effect on a test of attention and working memory assessed by the variable delayed response task. Donepezil at 160 μg/kg (i.m.) also failed to improve parkinsonian motor symptoms or L-DOPA-induced dyskinesias in the gold-standard parkinsonian MPTP-lesioned macaques. As a beneficial effect on falls was reported in parkinsonian patients receiving donepezil, we investigated the potential effects of donepezil administration on posture, measuring the angles of the neck and spine. Donepezil at 160 μg/kg (i.m.) actually counteracted an L-DOPA-induced improvement in neck and spine angulation. In summary, donepezil, at the doses tested, did not improve motor or non-motor symptoms of parkinsonism, had no effect on L-DOPA-induced dyskinesias and even had a tendency to worsen posture. In conclusion, these data suggest that the supposed effect of

donepezil on improving falls in parkinsonian patients is not directly attributable to an effect on motor symptoms or the cognitive capabilities currently tested.

Title: Stereological analysis of neuronal loss in the striatum of a transgenic Huntington's disease monkey model

Authors: *Y. CHEN[1], R. VILLABA[2], S. JENKINS[2], Y. SMITH[3], A. W. S. CHAN[1]; [1]Dept. of Human Genet. and Div. of Neuropharm. and Neurologic Di, [2]Div. of Neuropharm. and Neurologic Dis., [3]Dept. of Neurology, Emory Univ. Sch. of Medicine; Div. of Neuropharm. and Ne, Yerkes Primate Res. Center, Emory Univ., Atlanta, GA

Abstract: Striatal degeneration is the key pathological feature of Huntington's disease (HD), which is caused by expansion of CAG repeats in huntingtin (*HTT*) gene. In recent years, significant effort has been devoted towards the development of a transgenic nonhuman primate model of HD. However, it is not clear whether the atrophy of the striatum in these animals is similar to that seen in HD patients. To address this issue, we assessed the extent of neuronal degeneration in the striatum of two twin brother transgenic HD monkeys that express exon 1 of human *HTT* gene with 83 and 29 CAG repeats controlled by the human ubiquitin C promoter. We euthanized one monkey, which has 83 repeats at one year old and the other at five years-old due to the severe disease phenotypes including seizure, chorea, dystonia and weight loss etc. Our recent studies have shown a positive correlation between the number of *HTT* copies and the early age of onset of motor dysfunctions (dystonia, chorea) and respiratory difficulty. First, immunohistochemistry staining with the EM48 antibody, which raised specifically against the

mutant HTT with expanded CAG repeats, revealed dense aggregation of abnormal HTT expression/intranuclear inclusion bodies throughout the brain in the two HD monkeys. Second, we estimated the volume of the putamen and caudate nucleus using the Cavalieri's method, and determined the total number of neurons in various functional regions of the striatum using the optical fractional method based on unbiased stereological principles. For this series of experiments, the caudate nucleus and putamen were divided in different regions of interest based on their functional attributes. When compared with age-matched normal monkeys, preliminary analyses indicate that both the caudate nucleus and putamen of the two transgenic animals show a decreased volume and a major neuronal loss in both striatal components. A detailed quantitative analysis is in progress to determine the extent of these changes, and compare neuronal loss across various functional regions of the striatum. Our data suggest that some of the neuropathological signatures of transgenic HD monkeys are comparable to those described in HD patients. Thus, along with our longitudinal HD development studies, transgenic HD monkeys could be a unique model for determining neuropathogenesis and identifying biomarkers of HD progression, and for the development of new HD therapies.

Title: Chronic elevation of stress hormone accelerates the onset of memory decline in Huntington's disease mice

Authors: *C. MO[1,2], T. RENOIR[1], A. J. HANNAN[1,2];
[1]Behavioural Neurosci., Florey Inst. of Neurosci. and Mental Hlth., Melbourne, Australia; [2]Anat. and Neurosci., Univ. of Melbourne, Melbourne, Australia

Abstract: The onset of Huntington's disease (HD), a neurodegenerative disorder, can be predicted by the length of the causative trinucleotide repeat expansion. However, it is now known that environmental factors can also influence the onset of symptoms (cognitive, psychiatric and motor deficits). Few environmental factors have been identified. Recent data suggests that HD patients and mice show an abnormal stress response. We therefore

hypothesized that chronic treatment with corticosterone, modeling elevated stress levels, would accelerate symptom onset in HD mice.
R6/1 transgenic HD mice and wildtype littermates were treated with corticosterone dissolved in drinking water, or water alone. Treatment started from 6 weeks of age, before the onset of established cognitive, affective, sexual and motor impairments. Corticosterone (CORT) treatment did not affect sexually-induced vocalizations, affective or motor behaviours in either genotype. However, CORT-drinking HD mice developed Y-maze memory impairment earlier than water-drinking HD mice. CORT-drinking wildtype mice performed well and did not differ significantly from water-drinking controls. Hippocampal glucocorticoid and mineralcorticoid receptor mRNA, and BDNF mRNA and protein, were not altered by CORT-drinking.
The onset of memory deficits in HD mice was accelerated by CORT treatment, in contrast to wildtype littermate controls which were unaffected by the elevated CORT levels. This suggests that cognitive function in the HD brain is more vulnerable to stress-induced impairments. We present the first evidence that elevated levels of chronic stress hormone can accelerate any aspect of the HD phenotype. These findings suggest that clinical interventions which reduce stress, and associated hormone levels, may delay onset of cognitive deficits in HD individuals.

Title: AAV-mediated expression of RNAi confers long term suppression of Htt and ameliorates disease manifestations in the YAC128 mouse model of Huntington's disease

Authors: *L. M. STANEK[1], P. S. SARDI[2], B. MASTIS[2], A. RICHARDS[2], S. H. CHENG[2], L. S. SHIHABUDDIN[2];
[1]Genzyme Corp, FRAMINGHAM, MA; [2]Neurosci., Genzyme, a Sanofi Co., Framingham, MA

Abstract: Huntington’s disease (HD) is a fatal, autosomal dominant neurogenetic disorder. HD results from a polyglutamine repeat expansion in exon 1 of the huntingtin gene, conferring a toxic gain of function on the huntingtin protein (Htt). Currently, no therapies exist that address the underlying basis of HD. RNA interference (RNAi) has emerged as a potential therapeutic strategy to treat dominant diseases by specifically reducing expression of the offending gene product. Here, we tested whether RNAi induced by artificial microRNAs (miRNAs) could

reduce expression of mutant Htt in the YAC128 transgenic mouse model of HD and improve HD-associated behavioral deficits. Recombinant AAV vectors encoding a miRNA-based hairpin against the huntingtin gene (AAV-miRNA-htt) were delivered via direct intra-striatal injections into YAC128 mice or wild type littermate controls. Both motor and affective behaviors were evaluated and tissues were harvested for histological and biochemical analysis. Animals were sacrificed 1 and 5 months post injection. Histological analysis of brain sections from injected mice showed widespread vector transduction in the striatum at 1 and 5 months post-injection without overt neuroinflammation. Biochemical analyses performed on striatal extracts showed a significant reduction in both Htt mRNA and protein levels in mice injected with AAV-miRNA-htt compared to AAV-null injected controls, with equivalent levels of reduction at both 1 and 5 months post injection. This reduction in Htt levels was associated with improvements in DARPP-32 and D1 receptor transcript levels in the striatum suggesting restoration of transcriptional dysregulation, a key molecular feature of HD. Behavioral analysis revealed that YAC128 mice injected with AAV-miRNA-htt showed significant improvements in both the Rota-rod motor coordination test and the Porsolt swim test for depression. To evaluate if lowering Htt levels could reduce neuropathology in the YAC128 mice, mice were injected with AAV-miRNA-Htt or AAV-GFP vectors at 7 months of age and sacrificed at 12 months of age, when neuropathology should be present. Immunohistochemical analysis of brain sections showed a reduction in mHtt aggregates in AAV-miRNA-Htt treated mice but not AAV-GFP injected controls. Hence, AAV-miRNA-Htt significantly reduced Htt protein expression in the brain and improved biochemical and behavioral abnormalities as well as neuropathology in the YAC128 mouse model of HD. Together, these findings confirm the potential use of AAV-mediated expression of RNAi as a therapeutic for HD.

Title: Intranasal and intraperitoneal administration of a TrkB small molecule partial agonist improves motor coordination in a transgenic mouse model of Huntington's disease

Authors: *C.-T. CHIU[1], F.-F. LIAO[1], G. LINARES[1], F. M. LONGO[2], D.-M. CHUANG[1]; [1]NIMH, NIH, BETHESDA, MD; [2]Dept. of Neurol. and Neurolog. Sci., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: Huntington's disease (HD) is an inherited, lethal neurodegenerative disorder currently without effective treatment. It is caused by an abnormal polyQ stretch in the protein huntingtin and results in a gradual loss of neurons particularly in the striatum and cortex. Those afflicted suffer from emotional deterioration and uncontrollable movements. Transcriptional dysregulation plays a central role in the pathology of HD and decreased expression of brain-derived neurotrophic factor (BDNF) has been reported in the striatum of HD patients. BDNF is important for cell survival and synaptic plasticity, and is a key mediator of the clinical efficacy of antidepressant drugs. However, BDNF is considered a poor drug candidate because of its relatively short half-life in plasma, weak permeability to the brain, and potential side effects as a full agonist. In this study, we assessed the therapeutic potential of LM22A-4, a small non-peptide molecule that acts as a direct and specific partial agonist of the BDNF receptor TrkB, but not p75, in a widely-used transgenic mouse model of HD, N171-82Q. Intranasal application of this compound was recently reported to produce beneficial effects in animal models of traumatic brain injury, hypoxia-ischemia, and Rett syndrome. For drug treatment, LM22A-4 was dissolved in saline and administered both intranasally (5 mg/kg) and intraperitoneally (50 mg/kg) once daily starting from seven weeks of age. Motor coordination was measured using an accelerating rotarod apparatus. Compared with age-matched wild-type littermates, the performance of N171-82Q mice at six weeks was normal but became impaired progressively and significantly at 18 (147.5 ± 6.5 vs. 124.1 ± 7.3 sec) and 22 (145.9 ± 5.5 vs. 124.3 ± 8.3 sec) weeks ($n = 12$; $P < 0.05$, t-test). This deficit in motor coordination was dramatically rescued by long-term daily treatment with LM22A-4, and the performances of drug-treated N171-82Q mice measured at 18 (150.0 ± 8.8 sec) and 22 (147.5 ± 7.5 sec; $n = 12$) weeks were comparable to those of their wild-type littermates. Since the rotarod task largely depends on striatal function, it seems possible that improved motor coordination in HD mice could be attributable to neuroprotective effects of pharmacologic activation of TrkB by this compound. Effects of LM22A-4 on depressive-like behaviors and survival of these HD mice are under investigation. We will also determine the effects of LM22A-4 on the TrkB signaling pathway, apoptosis, and huntingtin aggregates in the brain of N171-82Q mice. Our findings will provide insight into the role of TrkB as a possible therapeutic target in this disease. This study was supported by the Research Fund of IRP, NIMH, NIH.

Title: Oligodendrocyte dysfunction in Huntington's disease mice

Authors: *B. HUANG, M. A. GAERTIG, X.-J. LI, S. LI;
Emory Univ., Atlanta, GA

Abstract: Huntington's disease is a neurodegenerative disorder that is caused by an expanded polyglutamine tract in the N-terminal region of huntingtin. It is characterized by cognitive and behavioral deficits, as well as movement disorders. While the effect of mutant huntingtin on neuronal function has been extensively studied, its effect on the function of glial cells remains to be fully investigated. There is evidence of white matter abnormalities in both HD patients and HD mouse models, suggesting that mutant huntingtin might affect oligodendrocyte function. We hypothesize that mutant huntingtin causes oligodendrocyte dysfunction, which contributes to the pathogenesis of the disease. To this end, we have generated transgenic mice that express an N-terminal fragment of mutant huntingtin exclusively in oligodendrocytes. These mice develop a tremor by 2 months of age and have locomotor and behavioral deficits, as well as body weight loss and reduced lifespan compared to control mice. Hypomyelination is present in the striatum of mutant mice, and preliminary data suggest that there is a dysregulation of myelin gene expression. These results suggest that the expression of mutant huntingtin in oligodendrocytes plays an important role in HD pathology.

Title: Characterization of the genotypes and behavioral phenotypes of mutant-huntingtin transgenic songbirds

Authors: *W.-C. LIU;
Rockefeller Univ., NEW YORK, NY

Abstract: Huntington's Disease (HD) is a neurodegenerative genetic disorder that causes neuronal degeneration and progressive motor or cognitive dysfunction. Using lentiviral-mediated human mutant-huntingtin (mHTT, 145Q) vectors, we have recently produced transgenic songbirds (canary and zebra finch) that show severe behavioral disorders, and some of these behavioral symptoms are similar to those of human HD patients. Here we aim to characterize the genotypes and behavioral phenotypes of the transgenic songbirds that are inserted with human mutant and wild-typed huntingtin (145Q and 23Q-HTT) genes. We identify DNA, RNA, and protein expression of mutant-HTT in transgenic birds, and determine how these genotypes are associated with vocal behavioral phenotypes. Behaviorally, the F1 transgenic zebra finches show four major vocal learning disorders: (1) sustained song variability in adulthood; (2) poor song imitation; (3) progressive song deterioration; and (4) "stuttering-like" serial repetition of song syllables. The vocal disorders of 145Q F1 birds are more severe than those of wild-type 23Q F1 transgenics. These results suggest that human mutant-HTT gene is associated with progressive vocal-motor learning disorders in songbirds. The vocal learning disorders and vocal deterioration observed in transgenic songbirds and the songbird's well-defined cortical-basal ganglia vocal circuits provide songbirds a great model system to study the neuropathology that underlies HD.

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder which is characterized by motor disturbance, cognitive decline and psychiatric manifestations. The disease typically starts in midlife and symptoms progress over the course of 15-20 years until death. HD is caused by a highly polymorphic CAG trinucleotide repeat expansion in the gene coding for the huntingtin protein, and aggregation of this protein, as well as gradual loss of (predominantly striatal) neurons are regarded as major hallmarks. For the investigation of disease mechanisms and potential therapeutic approaches, mouse models that recapitulate phenotypic features of human HD are crucial tools. The Q175 knock-in mouse, developed at PsychoGenics Inc. (NY, USA), contains an expanded CAG repeat (~179 CAG repeats), derived from a human mutant huntingtin allele, within the native mouse gene. In this HD model, first disease symptoms develop already at relatively young age and slowly progress over lifetime, rendering it suitable to study the course of pathological events triggered by the mutation. It has been reported that HD-like motor deficits and brain atrophy become apparent in homozygous mice by 2-3 months and in heterozygous littermates by 4-5 months of age. In order to characterize in more detail the underlying pathological processes in the heterozygous Q175 model on cellular level, we used a quantitative **immunohistochemical** approach to analyze brain sections of wild type and Q175 heterozygous mice up to 12 months of age. A series of imaging readouts were developed to detect number and morphology of particular cell types like medium spiny neurons, glial cells and oligodendrocytes in striatal and cortical regions of coronal brain sections. Furthermore, the abundance and distribution of soluble and aggregated huntingtin, labelled by antibodies against pan or mutant huntingtin, were monitored. Our detailed analyses demonstrate a progressive increase in mutant huntingtin aggregate load within the striatum and cortex of Q175 mice with age. In both brain areas, huntingtin aggregates appeared not only in the nuclear, but also in the perinuclear region of cells, with the strongest increase in aggregate number being detected between 6 and 8 months of age. However, despite the rise in aggregate load, we have neither observed degeneration of medium spiny neurons, nor any signs of inflammation as assessed on the basis of the number, morphology and size of astro- and microglia. To uncover potentially subtle changes in the CNS of the Q175 mouse model, it may be necessary to study additional biomarkers, and we are currently establishing respective imaging readouts for this purpose.

Title: Reversal of cognitive deficits in the Hdh^{Q111} mouse model of Huntington's disease by an α5-$GABA_A$ receptor inhibitor

Authors: R. C. MITCHELL[1], *O. F. MONTEIRO[1], J. WALLACE[1], L.-A. ETHERINGTON[1], S. SCHWEIGER[1,2], J. J. LAMBERT[1], R. F. LANGSTON[1];

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder caused by a mutation in exon 1 of the huntingtin gene resulting in an increased number of CAG repeats (>36), leading to aberrant huntingtin protein production and aggregation. HD is traditionally characterised and diagnosed by movement disturbances, however cognitive abnormalities often present prior to locomotor dysfunction and may occur, in part, through changes within the hippocampus [1]. We assessed cognitive abnormalities in the Hdh^{Q111} mouse model of HD in which exon 1 of the huntingtin gene contains 111 CAG repeats. Cognition was assessed in two age groups (1.5 and 3 month old mice) using a suite of novel object recognition tasks in wild type (WT) and heterozygous (HET) mice. Both young (1.5 month) WT and HET mice performed all the tasks and their behaviour was indistinguishable. For older WT mice (3 months) performance was maintained on all tasks, but HET mice now performed at chance levels on tests of hippocampal-dependent memory. Furthermore, hippocampal CA1 long term potentiation was impaired in HET mice *cf.* WT. The hippocampus exhibits dense expression of α5-$GABA_A$Rs [2] and drugs inhibiting this $GABA_A$R subtype are known to enhance cognition [3]. 3 month old WT and HET mice were treated with the α5-$GABA_A$R inverse agonist α5IA, or vehicle. Although the drug had no effect on the performance of WT mice, it successfully alleviated all the cognitive deficits exhibited by HET mice. These data identify the α5-$GABA_A$R as a viable target for treating the cognitive symptoms of HD.

Title: Ganglioside GM1 ameliorates non-motor symptoms in the YAC128 model of Huntington disease

Authors: M. ALPAUGH[1,2], P. KAR[1], D. GALLEGUILLOS[1,2], M. HORKEY[1], B. KERR[2,3], *S. SIPIONE[1,2];

Abstract: Huntington disease (HD) is a neurodegenerative disorder that results in motor, cognitive and psychiatric deficits. The disease is caused by the expansion of a polyglutamine stretch in huntingtin, a ubiquitous protein with unclear functions.
The molecular mechanisms underlying neurodegeneration in HD are complex and include transcriptional dysregulation, mitochondrial dysfunction, impaired intracellular and axonal transport, as well as aberrant signaling and neurotransmission.
We recently demonstrated that the synthesis of ganglioside GM1, a lipid highly enriched in the brain, is also impaired in a variety of HD models. Restoration of normal GM1 levels by chronic intra-ventricular infusion of the ganglioside, abolished the pathological motor phenotype in already symptomatic YAC128 mice, a well characterized transgenic model of HD. These dramatic effects on mouse motor behaviour were accompanied by phosphorylation of mutant

huntingtin at Ser13 and Ser16, a post-translational modification that has been shown to decrease mutant huntingtin toxicity. This suggests that GM1 might be able to modify the course of HD and also correct non-motor symptoms of the disease.
Our preliminary data support this hypothesis. In the YAC128 model, significant attenuation of cognitive and psychiatric symptoms associated with HD was observed after administration of GM1 for 14 days. YAC128 mice treated with GM1, but not with vehicle, performed as well as wild-type mice in tests that measure anxiety (elevated plus maze, open field, and novelty induced hypophagia), cognition (y-maze, novel mouse approach), and depression (forced swim test). Overall, our data suggest that GM1 is a disease-modifying treatment that is able to ameliorate not only motor dysfunction, but also cognitive and psychiatric deficits in YAC128 mice.

Title: Impaired thermoregulatory capacity in R6/2 and zQ175 mouse models of huntington's disease during cold challenge

Authors: J. PUOLIVÄLI[1], E. HOHTOLA[2], *O. M. KONTKANEN[1], L. C. PARK[3], T. HEIKKINEN[1];

Abstract: Huntington's disease (HD) patients display clinical signs of disturbed energy metabolism, and similar changes have been observed in transgenic HD mouse models. Negative energy balance in HD may cause body weight decrease and loss of muscle bulk. Here we studied the energetic profile of two different HD mouse models, transgenic R6/2 and zQ175 knock in (KI) HOMO and HET mice, as well as WT control mice. Resting oxygen consumption (VO_2) and carbon dioxide production (VCO_2) were measured by indirect calorimetry at thermoneutral zone (+32°C) and during cold stress (slow cooling from 32 to +ca. 3°C). The basal metabolic rate (BMR) at thermoneutrality was measured and compared to maximal energy use during the cold challenge. In addition, the body temperature (Tb) was measured with a rectal probe during challenge (at +32°C, +20°C, and +3°C). RQ (respiratory quotient, CO_2 produced/O_2 consumed)

and metabolic scope (VO_2 Max/BMR) values were also calculated. R6/2 mice were measured at 12 weeks old, and zQ175 KI mice at 12 months old. R6/2 and HOMO zQ175 KI mice showed increased mass-specific BMR at thermoneutrality compared to WT mice. In addition, R6/2 mice also showed decreased mass-specific maximum energy expenditure under cold challenge, and both R6/2 and KI HOMO mice showed decreased metabolic scope. However, KI HET mice had BMR and metabolic scope values similar to WT mice. We also found that R6/2 mice had extremely decreased Tb values during cold challenge; whereas, the Tb in KI mice maintained similar to WT mice. The absolute energy expenditure over the whole temperature range (+32 to +3°C) was linearly correlated in WT and KI mice, but not in R6/2, suggesting the thermogenic capacity in R6/2 is compromised. In summary, aged R6/2 and zQ175 KI HOMO mice both display increased metabolic rate at thermoneutrality, and R6/2 mice also lower maximum metabolic rate during cold stress. Thermogenic capacity in HD with energetic deficiency may be a useful screening tool for potential therapeutic compounds, particularly those that potentiate energy metabolism.

Title: Immunohistochemical characterization of R6/2 transgenic and zQ175 knock in mouse models of Huntington’s Disease

Authors: *M. CERRADA-GIMENEZ[1], L. TÄHTIVAARA[1], L. C. PARK[2], D. HOWLAND[2], I. MUÑOZ-SANJUAN[2], O. KONTKANEN[1], N. VARTIAINEN[1];
[1]Charles River Discovery Res. Services Finland Ltd, Kuopio, Finland; [2]CHDI Fndn. Inc., Los Angeles, CA

Abstract: Huntington's disease (HD) is accompanied by several tissue, cell type and pathway dysfunctions. Increased inflammatory response, oxidative and nitrosative stress, as well as altered iron metabolism are associated with the disease progression. We have immunohistochemically and histologically characterized changes in neuroinflammatory response in the brain of two HD mouse lines: widely-used R6/2 transgenic and a recently introduced zQ175 knock in (KI) mice (Heikkinen et al., *Plos One* 2012:7(12):e50717; Menalled et al., *Plos*

One 2012:7(12):e49838). The disease phenotype in the R6/2 mouse is early-onset and rapidly progressing, while the zQ175KI mouse exhibits a late-onset of symptoms that more closely mimic those in HD patients. zQ175 KI mice show age and genotype-related cognitive deficit as well as striatal atrophy at 8-10 months of age, so we wanted to evaluate the immunohistochemical markers at the same age range. R6/2 and zQ175KI mouse brain tissues were collected at different
ages: 4, 8 and 12 weeks for R6/2 and 3, 6 and 9 months for zQ175 KI mice. For basic characterization the neuronal marker NeuN and the astroglial marker GFAP were used. Further characterization involved immunohistochemistry for HD-associated markers like DARPP-32 (dopaminergic neurons), EM-48 (huntingtin protein), reactive nitrogen species-related markers nitrotyrosine, as well as inflammatory cell (microglial) marker Iba-1. Furthermore, immunohistochemical analysis for the iron storage protein ferritin and histological Perls staining for iron were used. The different immunostainings were analyzed for number of immunoreactive cells (NeuN, GFAP, Iba-1), size of immunopositive cells (Iba-1), staining intensity or amount of immunoreactivity (DARPP-32). In R6/2 mice, stereological analysis of Iba-1 revealed increased soma size, a clear sign of activated microglia, when compared to wild-type littermates. The immunoreactivity of ferritin was significantly increased in the R6/2 mice, and the cell morphology was similar to activated microglia. The immunoreactivity of DARPP-32 in striatum was significantly decreased in R6/2 mice when compared to wild-type mice. Our study provides new information on the inflammatory and oxidative damage during disease progression in two HD mouse models. Several of the immunohistochemical markers used may be useful as biomarkers when evaluating disease progression and compound efficacy in preclinical models.

Title: Progressive motor impairment in transgenic Huntington disease monkeys

Authors: J. BACHEVALIER, T. CHI, E. HEIDI, S. MORAN, *A. W. CHAN;
Yerkes Center/Emory Univ., ATLANTA, GA

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder caused by the expansion of polyglutamine (CAG; Q) repeat within the coding region of the Huntingtin (*HTT*) gene. HD is a devastating disorder with progressive decline in motor, cognitive and psychiatric functions. This paper reports a longitudinal study of motor functions in a transgenic HD nonhuman primate (HD-NHP). rHD1, a HD-NHP expressing exon 1 of human *HTT* gene with 29Q regulated by a human ubiquitin C promoter. rHD6, 7 and 8 express Exon 1-10 of the *HTT* gene containing 73Q under the control of human *HTT* promoter. Additionally, four age-matched control NHPs were used for comparisons. All animals were tested at different points during development to follow their neurobehavioral and motor development. Except for the INAS and JNAS task that were performed in the infant nursery, all other tasks were conducted in a sound-attenuated room equipped with a white noise generator to reduce external noise, except otherwise mentioned. Animals were transferred to a Wisconsin General Testing Apparatus, facing a test tray onto which objects or equipment could be positioned. Rewards were either peanuts, raisins, fruity gems, mini M&M, Marshmallows, depending on animal's preference, or a ring-shaped candy ("Lifesaver") for the ***Visuospatial orientation*** task at 16 and 36 months. The result showed that rHD1 had neuromotor responses and motor activities similar to those of controls, the rest other three HD infant displayed slightly reduced neuromotor responses in Week 3 and 5 ($U = 2$, $p < .04$ and $U = 1$, $p < .04$) and poorer motor control at all weeks (all $p_s < .03$ for Weeks 2-5). The neuromotor responses of the 3 HD-NHPs improved slowly with age but never reached the strength of those of the control animals [Group effect: $F(1, 6) = 12.46$, $p < .01$]. At 16 months, rHD1 showed no impairment in the Detour/Barrier task, whereas more problems emerged in the other 3 HD-NHPs. They displayed significantly greater motor problems when attempting to retrieve the food rewards in all trials [$U = 0.5$, $p = .04$ and $U = 0$, $p = .026$, for easy and difficult trials, respectively]. The latency and the fastest time to free the lifesaver and the number of failure at 16 months did not differ between groups, with all four HD-NHPs performing as well as the control animals. By 36 months of age, however, HD-NHPs required longer time to free the candy when more difficult patterns were used [$t(5) = 3.73$, $p = .014$, for latency]. Our study shows a consistent progression of motor impairments in HD-NHPs. The data provide the first primate model that replicates progression of HD in human based on longitudinal behavioral measurements. Grant supports: RR-00165 and RR-018827.

Title: Functional imaging in awake mice: Studies on a transgenic (Q175) mouse model of Huntington's disease

Authors: *C. F. FERRIS[1], T. M. BARCHET[1], S. TODDES[2], P. KULKARNI[1], J. YEE[1], W. KENKEL[1], M. NEDELMAN[3];
[1]Psychology, Northeastern University, Ctr. for Translational NeuroImaging, Boston, MA; [2]Animal Imaging Res., Westminster, MA; [3]Ekam Imaging, Boston, MA

Abstract: Functional magnetic resonance imaging (fMRI) is a powerful and widely-used tool for investigating changes in brain function and structure in humans. Functional fMRI is also becoming more commonly used to study the neurobiology of the brain in awake rats and non-human primates. However, there are very few, if any, published reports on the functional connectivity, tractography, quantitative anisotropy or functional brain imaging in awake mice. To address this need, we developed a combined radiofrequency coil and mouse restraining system for awake imaging, together with a 3D segmented and annotated mouse atlas and software for computational data analysis of over 100 discrete brain areas for C57BL mice. This technology was applied to the characterization of the transgenic Q175 mouse model of Huntington's disease imaged at 7.0T (300 MHz). Wild type, heterozygous and homozygous Q175 mice were acclimated to the restrainer and imaging protocol before a scanning session. The stability of the data (motion detection) as estimated by a 3D rigid body model with six degrees of freedom for translational and rotational movement was determined for all animals (n=28) and was less than 20 μm and 1.5-3 degrees. Blood Oxygen Level Dependent (BOLD) data was obtained with a multi-slice, single-shot Fast Spin Echo pulse sequence using a partial Fourier acquisition with a 9/16 ratio. Twenty, 0.75 mm thick, axial slices were collected every six seconds. With a FOV of 2.5 cm and a data matrix of 96 x 96, the in-plane pixel resolution for these studies was 260 μm2. A surrogate BOLD response was elicited by the presentation of 5% CO2 and revealed robust signal changes (>6%) in all animals. Animals challenged with the odor of ferret to elicit the innate fear response and the odor of almond to activate neural circuitry involved in motivation and reward (Kulkarni et al. Behav. Brain Res, 230:201, 2012) show significant increases and decreases in BOLD signal in brain areas involved in emotional experience and cognition. Diffusion tensor imaging (DTI) with quantitative anisotropy was performed to detect differences in brain microarchitecture between the different groups. To do so, we used a novel method of analysis in which different indices of anisotropy (IA), e.g. ADC, FA, λ1, RA from over 20,000 voxels were registered into the mouse atlas. There were significant differences in IA values in multiple areas of the brain between the wild-type controls and homozygous Q175. These data support the use of non-invasive MRI in awake mice and open up

the possibility for assessing the efficacy of new therapeutics on the myriad of transgenic mouse models for psychiatric and neurological disorders.

Sch. of Med. and Homeopathy IPN, Mexico, Mexico

Abstract: Essential fatty acids (EFAs) exert experimental and clinical neuroprotection in neurodegenerative diseases as Huntington's disease (HD). The main EFAs; oleic acid (OA), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) contained in olive and fish oil, are inserted into the cell membranes and they act as agonists of nuclear receptors. Althought that EFAs confer neuroprotection, the exact mechanism is still unknown. The aim of this work was to

evaluate the neuroprotection given by a diet rich in EFAs, by means of in vitro (synaptosomes) and in silico models, evaluating the membrane insertion of EFAs and the induction of nuclear signals. Male Wistar rats (140-150 g) were fed during 20 days with control diet or EFAs enriched diet contained in olive or fish oil (15% w/w). Synaptosomes viability was evaluated by electron microscopy and measured gamma-glutamyl transpeptidase activity was measured. Synaptosomes lipid profile showed a 21.9% OA enrichment for the group of olive oil and 0.12% of EPA in fish oil group compared to the control diet. Membrane fluidity evaluation, showed reduced anisotropy in enriched synaptosomes. Synaptosomes incubation with quinolinic acid (QUIN, an agonist NMDA receptor), showed significant oxidative reduction in enriched EFAs group compared with control. Finally significative expression of gamma isoform of peroxisome proliferator activated receptors (PPARy) was detected in EFAs-enriched striata tissue vs control. Molecular dynamics simulations were performed in parallel, inserting DHA and EPA systems in a reduced membrane model (DPPC). These results suggest that EFAs enrichment confers antioxidant effect, involving membrane integrity and induction of PPARy.

Title: Early abnormal striatal gene expression in BACHD rats recapitulates the human disorder and reveals multiple mechanisms of gene dysregulation in Huntington Disease

Authors: *L. YU-TAEGER, M. BONIN, O. RIESS, H. P. NGUYEN;
Inst. of Med. Genet. and Applied Genomics, Univ. of Tuebingen, Tübingen, Germany

Abstract: Huntington Disease (HD) is an autosomal dominant inherited neurodegenerative disorder caused by an expansion of CAG repeats in the HTT gene. The mutant huntingtin protein

(htt) has been proposed to cause neuronal dysfunction and neuronal loss through multiple mechanisms. Transcriptional changes may be a core pathogenic feature of HD. Utilizing the Affymetrix platform we performed a genome-wide RNA expression analysis in two BACHD transgenic rat lines at 12 months of age, which carry full-length human mutant huntingtin with different expression levels. Microarray results were validated through real-time PCR with another cohort of rats, showing up- and downregulation in numerous striatal genes in BACHD rats compared to wild type controls. Comparison with data from human HD brains revealed a high concordance in distinct canonical pathways and functional categories, while the analysis of upstream regulators identified these abnormalities to be involved in multiple mechanisms including cytokine signaling and growth factor signaling. Results of this study demonstrate that this BACHD rat model recapitulates accurately gene expression changes of the human disease and therefore supports its application in preclinical research. Additionally, our results point to previously unknown mechanisms in gene dysregulation and may provide novel insights into HD pathogenesis.

Title: HD-SELECT, a novel patient-derived cell model enabling disease-modifying drug selection for Huntington’s disease

Authors: C. BISCARRAT[1], *N. COMPAGNONE[2];
[1]Translational medicine, [2]ICDD, MEYREUIL, France

Abstract: Huntington’s disease (HD) is an autosomal dominant monogenetic disease that alters muscle coordination and leads to striatal neurodegeneration and dementia. HD may begin with uncontrolled movements in the fingers, feet, face or trunk, but it also affects the patient’s judgment, memory and other cognitive functions. HD progression results in slow degeneration in

neurons controlling emotions, cognitive functions and coordination of movements, leading to death of patients, mostly due to malnutrition, in an average of 16 years.
Lack of translatable models for complex neurodegenerative diseases has contributed to drug development failure in HD. Animal models fail to recapitulate the disease progression and complexity as seen in humans, while *in vitro* models, generally focused on a molecular target, only partially mimic the disease etiology. However, over the last decade, both have largely increased our understanding of HD pathophysiological mechanisms, as well as the number of drug development programs targeting HD. Finding a cure for HD is crucial, and the biotech and pharma industries lack proper models to guide the selection of disease-modifying drugs. To this aim, ICDD identifies and develops patient-derived cell models that enable the exploration of disease-modifying property from small molecules or biologics. Using a system biology approach and a proprietary cellulomic technology, Mitostream®, a HD signature was identified from a pilot cohort of 12 patients. The cohort included Caucasian female patients 38.17 +/- 12.6 years of age with an average duration of the disease at the time of biopsy of 3.7 years +/-10.3 years. Age-matched controls ranged 36.33 +/- 14.4 years of age. No other diseases or co-morbidity were reported in the HD group, while a minor depression was reported in the healthy group. Data reduction and identification of the discriminating variables were obtained through the use of different complementary strategies using principal component analysis, hierarchical cluster classification and discriminant analysis. It generated a HD specific disease-signature of 7 variables that defined the group of HD patients and that could be partially reversed with reference compounds. The signature specificity was tested in a larger population of 32 patients including patients with other neurodegenerative diseases and proved specific for HD. The model was stable and the signature robust over time, making the developed HD-select model a good tool for disease-modifying compound selection.

Title: Genetic knockdown of HDAC4, or sub-chronic treatment with a novel selective Class IIa HDAC inhibitor, reverses elevated membrane excitability in striatal medium spiny neurons from R6/2 and zQ175 Huntington’s disease model mice

Authors: *G. C. TOMBAUGH[1], S. GELMAN[1], A. BRADAIA[2], K. WADEL[2], V. GARDES[2], C. TOULLER[2], A. SERS[2], A. GHAVAMI[1], B. BUISSON[2], G. BATES[3], M. MIELCAREK[3], C. DOMINGUEZ[4], M. MAILLARD[4], V. BEAUMONT[4];

Abstract: Huntington's disease (HD) is a lethal autosomal dominant neurodegenerative disorder that leads to deficits in motor control widely believed to reflect structural and/or functional changes in neurons of the basal ganglia. In-vitro brain slice recordings of both the R6/2 and zQ175 mouse models of HD have revealed changes in intrinsic membrane properties of striatal medium spiny neurons (MSNs), which are selectively vulnerable in HD. Among these changes is a large increase in membrane resistance (Rm) and a reduced rheobasic current (Rh), defined as the minimum depolarizing current needed to elicit an action potential. Such changes may result in aberrant processing of excitatory input to the striatum. Genetic-knock down of HDAC4 restored these and other electrophysiological changes in both the R6/2 model, a transgenic over-expresser of Exon 1 HTT with an expanded polyglutamine repeat, and heterozygous zQ175 knock-in mice, which carry one normal and one mutant HTT allele with an expanded repeat of ~190 polyglutamines, in addition to reversing behavioral alterations in R6/2 mice.
We examined MSN properties in R6/2 mice and zQ175 heterozygous knock-in mice after sub-chronic in vivo exposure (4 weeks or 4 months respectively) to a novel selective Class IIa HDAC inhibitor, CHDI-00390576 (up to 100mg/kg, p.o., bid) to evaluate whether this could mimic the genetic HDAC4 knockdown data. Whole-cell recordings from visually identified MSNs were performed in slices from 8w old R6/2 mice and 6mo old Q175 mice and respective WT littermates, 1day - 2 weeks following drug washout. MSNs in R6/2, Q175 and WT mice had nearly identical resting membrane potentials, but R6/2 and Q175 MSNs exhibited significantly elevated Rm and lower Rh. Rm in both models was partially reversed by CHDI-00390576; Rh was partially reversed in R62 but not significantly in Q175. Neither Rm nor Rh was affected in drug-treated WT mice. Action potential amplitude and threshold in the HD models were decreased and increased, respectively, relative to WT controls. These changes, which were reversed in HDAC4 knockdown Q175 mice, were unaffected in drug-treated R62 mice. In R62 input-output curves for EPSCs evoked by cortical stimulation (layer V-VI) saturated at a lower amplitude, and mEPSC frequency was significantly lower compared to WT MSNs, but no drug-related rescue was seen for either measure. In contrast, reduced mEPSC frequency was reversed by HDAC4 knockdown in both R62 and Q175. These findings indicate that disease-specific HD phenotypes in MSNs can be partially reversed by manipulating HDAC4 activity/expression in R6/2 and Q175 mice, suggesting a therapeutic potential for Class IIa HDAC inhibitors in HD.

Title: The expression of mutant SOD1 in astrocytes negated the noradrenaline-induced astrocyte-mediated neuroprotection

Authors: *Y. YOSHIOKA, M. AKUNE, T. YOSHIDA, A. YAMAMURO, Y. ISHIMARU, S. MAEDA;
Setsunan Univ., Hirakata, Japan

Abstract: It has been reported that dysfunction of astrocyte might be one of the cause of motor neuron degeneration in the transgenic SOD1 (G93A) mouse model of amyotrophic lateral sclerosis (ALS). The reduction
of glutathione (GSH) has been also reported in the spinal cord of mutant G93A-SOD1 transgenic mice. Recently, we found that noradrenaline (NA) protected neurons from H_2O_2-induced death by increasing the supply of GSH from astrocytes by using the co-culture system of human neuroblastoma SH-SY5Y cells and human astrocytoma U-251 MG cells. We hypothesize that NA-induced astrocyte-mediated neuroprotection might be impaired in familial ALS. To reveal the hypothesis, in this study, we investigated the effect of mutant SOD1 (G93A) expression in U-251 MG cells on the neuroprotective effect of NA by using the co-culture system. We established U-251 MG cells overexpressed wild-type or mutant (G93A) human SOD1 and SH-SY5Y cells overexpressed green fluorescence protein (GFP). The viability of SH-SY5Y cells was determined based on the morphology of GFP-positive cells under a
fluorescence microscope. To investigate the changes of intracellular GSH level in SH-SY5Y cells in co-culture, the cells were stained with reduced GSH-reactive probe monochlorobimane, and were analyzed by Cellomics ArrayScan. NA (10 μM) increased intracellular GSH levels in U-251 MG cells expressing wild-type SOD1, but not in the cells expressing mutant SOD1. In co-culture of SH-SY5Y cells and U-251 MG cells expressing wild-type SOD1, NA (10 μM) increased intracellular GSH levels of SH-SY5Y cells and protected the cells from H_2O_2-induced death. On the other hand, in co-culture using U-251 MG cells expressing mutant SOD1, NA (10 μM) neither affected intracellular GSH levels of SH-SY5Y cells nor protected the cells from H_2O_2-induced death. These results suggest that mutant SOD1 negated NA-induced astrocyte-mediated neuroprotection by inhibiting the increase of GSH in astrocytes. These findings indicate that dysfunction of the neuroprotective system induced by NA might be one of the cause of motor neuron degeneration in familial ALS.

Title: Deleting ephrin-b2 from reactive astrocytes is beneficial in ALS

Authors: L. SCHOONAERT[1,2], L. POPPE[1,2], A. VAN HOECKE[3], *W. L. ROBBERECHT[4,1,2]; [1]Lab. of Neurobiology, Vesalius Res. Center, VIB, Leuven, Belgium; [2]Exptl. Neurol. (Department of Neurosciences) and Leuven Res. Inst. for Neurosci. and Dis. (LIND), Univ. of Leuven (KU Leuven), Leuven, Belgium; [3]Max-Planck-Institute of Neurobio., München, Germany; [4]Dept Neurol., Univ. Hosp Gasthuisberg, 3000 Leuven, Belgium

Abstract:
Recently it has been shown that the EphA4 receptor is a modifier of ALS. Genetic and pharmacological inhibition of EphA4 rescues the phenotype in the zebrafish model of ALS and increases survival in ALS rodent models. In ALS patients an inverse correlation was found between EphA4 expression and disease onset. However, it is not yet fully elicidated what the mechanism of action is. Remarkably it is known that EphA4 interacts both with ephrin-a and ephrin-b ligands, wich are also bound to the cell membrane by a GPI-anchor or a transmembrane domain respectively. Several of the EphA4 interaction partners have been shown to be expressed on reactive astrocytes, microglia and oligodendrocytes. These cells play an important role in the pathogenesis of ALS and surround motor neurons which abundantly express EphA4. A promising candidate was ephrin-b2 as it has been shown to be highly expressed by reactive astrocytes after spinal cord injury. In the spinal cord of WT SOD1 mice ephrin-b2 was highly

expressed in motor neurons while only faint expression could be detected in astrocytes. At symptomatic stages the expression pattern changes and high immunoreactivity could be detected in astrocytes while the neuronal expression diminished. Similar results were obtained in spinal cords from ALS patients and controls. Although the expression pattern of ephrin-b2 changes during disease progression, the overall expression stays the same as checked by RT-PCR analysis. We hypothised that deleting ephrin-b2 from reactive astrocytes might have a beneficial effect on ALS. For this purpose we crossed the conditional ephrin-b2 knockout mouse with a GFAP-specific Cre-line and the $SOD1^{G93A}$ ALS model. Even though the GFAP-Cre promoter shows leaky expression, we find delayed disease onset and prolonged disease duration. These results suggest that ephrin-b2 might play a role in modifying Amyotrophic Lateral Sclerosis, but it will need further investigation.

Title: Calpain-dependent cleavage of TDP-43 plays a crucial role in ALS pathology

Authors: *T. YAMASHITA[1,3,2], T. HIDEYAMA[2], S. TERAMOTO[1,3,2], J. TAKANO[4], N. IWATA[5], T. C. SAIDO[4], S. KWAK[1,2,6];

Welfare, Chiba, Japan

Abstract:
TAR DNA-binding protein (TDP-43) pathology is the pathological hallmark of sporadic ALS,

but the underlying mechanism is poorly understood. Notably, TDP-43 pathology and reduced expression of adenosine deaminase acting on RNA 2 (ADAR2), the RNA editing enzyme responsible for adenosine-to-inosine conversion at the GluA2 glutamine/arginine (Q/R) site, concomitantly occur in the same motor neurons in ALS patients, suggesting a link between these two ALS-specific molecular abnormalities. AMPA receptors containing Q/R site-unedited GluA2 in their subunit assembly are Ca^{2+}-permeable, and motor neurons lacking ADAR2 undergo slow death, suggesting a role of Ca^{2+}-permeable AMPA receptor-mediated neuronal death mechanism in the ALS pathogenesis.
We found that Ca^{2+}-dependent serine protease calpain cleaved TDP-43 at the C-terminal region, and resulting N-terminal fragments were aggregation-prone. Notably, TDP-43 was absent from the nucleus forming aggregates in the cytoplasm of the motor neurons in a manner dependent on calpain activation in conditional ADAR2 knockout (AR2) mice, a mechanistic ALS model in which the ADAR2 gene is targeted in cholinergic neurons including motor neurons. Abnormal processing of TDP-43 was inhibited when the Ca^{2+}-impermeable AMPA receptors was expressed or when calpastatin, the endogenous calpain inhibitor, was overexpressed, but conversely, TDP-43 mislocalization was exaggerated when calpastatin was knocked out. Calpain cleaved TDP-43 at several positions in the C-terminal region, and calpain-dependent TDP-43 fragments were demonstrated in the brains and spinal cords of ALS patients. Taken together, the calpain-dependent cleavage of TDP-43 plays a crucial role in ALS pathology.

Title: FUS-regulated region- and cell-type-specific transcriptome is associated with cell selectivity in ALS/FTLD

Authors: *Y. FUJIOKA[1], S. ISHIGAKI[2], A. MASUDA[3], Y. IGUCHI[2], T. UDAGAWA[2], H. WATANABE[2], M. KATSUNO[2], K. OHNO[3], G. SOBUE[2];

[1]Nagoya Univ., Nagoya, Japan; [2]Neurol., [3]Neurogenetics, Nagoya Univ. Grad. Sch. of Med., Nagoya, Japan

Abstract: Amyotrophic
lateral sclerosis (ALS) is characterized by selective motor neuron degeneration in the primary motor cortex, brainstem and spinal cord. FUS is the causative gene of familial ALS and pathologically linked to sporadic ALS and frontotemporal lobar degeneration (FTLD). FUS is an RNA binding protein which was reported to function in transcription, RNA splicing, and RNA transport. Accumulated lines of evidence have suggested that altered RNA metabolism would be in the center of ALS/FTLD pathogenesis. To clarify the RNA metabolism cascade regulated by FUS in ALS/FTLD, we compared the FUS-regulated profiles of gene expression and alternative splicing in different primary cells from the central nervous system. FUS differentially regulated more genes in motor neurons, cortical neurons, and glial cells than in cerebellar neurons. The profiles of FUS-mediated alternative splicing in cortical neurons were quite similar to those in motor neurons, but not in glial cells or cerebellar neurons, whereas FUS-mediated gene expression profiles were similar among cortical neurons, motor neurons, and glial cells. FUS-mediated regulation of alternative splicing and gene expression likely determines vulnerability of cells and cellular response, respectively. We found that the Fus-binding-positions on target splicing exons were similar between glial cells and cortical neurons. Certain neurological diseases-associated genes, including *Mapt, Stx1a,* and *Fmr1,* were regulated by FUS. Our results indicate that FUS-regulated transcriptome profiles seem relevant to cell vulnerability in FUS-associated ALS/FTLD. Identified RNA targets for FUS could be therapeutic targets for ALS/FTLD.

Title: Modification of disease onset and progression for ALS by human chromogranin B variants

Authors: *Y. OHTA, D. PHANEUF, J.-P. JULIEN;
Psychiatry and Neurosci., Ctr. de recherce du CHU, Laval Univ., Quebec, QC, Canada

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive, fatal neurodegenerative disease that is characterized by selective loss of central and peripheral motor neurons. Although most cases of ALS are sporadic (sALS), approximately 15-20% of familial ALS (fALS) cases hold a variety of genetic mutations in the Cu/Zn superoxide dismutase (SOD1) gene. The mechanism whereby mutant SOD1 causes specific degeneration of motor neurons remains unclear, but it is believed that disease is due to a gain of a toxic function of mutant SOD1 protein. Recently, we discovered that chromogranin A and B interact specifically with different mutant forms of SOD1 (Urushitani M, et al. 2006) and that ALS patients carrying the P413L human chromogranin B (hCgB) variant develops disease nearly ten years earlier than ALS patients without this variation (Gros-Louis F, et al. 2009). The P413L hCgB is the first genetic variation documented to influence the age of onset in both fALS and sALS. Here, we further investigated the role of hCgB variants as modifier of disease onset and progression for ALS. Cell transfection experiments demonstrated the defective ability of hCgB variants to bind to mutant SOD1 and the defective sorting and maturation of hCgB variants into secretory granules. We generated transgenic mice overexpressing genomic fragments encoding the hCgB variants and crossed them to G37R-SOD1 mice to examine the effects of hCgB variants in mutant SOD1-mediated disease. So far, our analyses of Kaplan-Meier curves for disease onset and for survival of doubly Tg mice co-expressing mutant SOD1 with either P413 hCgB or L413 hCgB variants are consistent with the view that hCgB expression level and polymorphism are factors that may influence ALS disease onset or duration.

Title: Investigation of the role carbonic anhydrase 1 plays in motor neuron function and ALS pathology

Authors: *J. LIU[1], X. LIU[1], R. P. BOWSER[2], R. G. MILLER[3], T. KADOWAKI[1]; [1]Deprtment of Biol. Sci., Xi'An Jiao-Tong Liverpool Univ., Jiangsu, China; [2]Barrow Neurolog. Inst., Phoenix, AZ; [3]Forbes Norris MDA/ALS Res. Ctr., San Francisco, CA

Abstract: Carbonic anhydrase I (CA1) is the cytosolic form of the 16 isoforms of α-CA family in mammalian cells. CA is a zinc metalloenzyme that catalyzes the reversible conversion of CO_2 and H_2O to HCO_3^- and H^+ and is important in maintaining cellular pH homeostasis. CA2-deficiency in human causes Marble Brain syndrome with symptoms of osteopetrosis, renal tubular acidosis, and mental retardation. Other forms of CA including the membrane-associated CA9 and mitochondrion-resident CA5 have been indicated in cancer and obesity, respectively. Whether and how CA1 mightbe involved in ALS pathology is completely unknown. The objective of the study is to determine CA1 expression in human spinal cord and further investigate the potential mechanisms by which CA1 might be involved in ALS pathology. Methods: Immuohistochemical and/or immunofluorescent staining were used with human spinal cord section. Subcellular fractionation method was used to extract cytosolic and membrane-bound CA1s from spinal cord tissues. N2a-stable cell line was established to express human CA1 and Western analysis was carried out to examine ER stress responses. Transgenic *Drosophila* line of UAS-CA1 construct was generated by BestGeneInc. GMR and D42-GAL4 lines were purchased from Bloomington *Drosophila* Stock Center at Indiana University. Results: 1) CA1 protein level is significantly decreased in ALS spinal cord; 2) For the first time, we show that CA1 is expressed in human spinal cord motor neurons while CA2 is expressed outside the motor neurons; 3) In addition, CA1-immnuohistochemical staining in the motor neurons exhibit punctated instead of the diffused pattern as predicted. Further staining with subcellular organelle markers demonstrates the colocalization of CA1 with an ER-lumen protein PDI; 4) Biochemically, membrane-associated CA1 is increased to a greater degree than the cytosolic CA1 in ALS spinal cord. In contrast, CA2 is not changed in either the cytosolic or membrane-associated fraction between ALS and control subjects; 5) In N2a cells, expression of human CA1 decreases mutant SOD1-induced ER stress marker proteins BiP and phosphorylated eIF2α; 6) In *Drosophila*, eye-specific expression of human CA1 results in no observable phenotype while motor neuron-specific expression causes 54% reduction in the number of the hatched embryos. Conclusion: our studies suggest that CA1 may have important regulatory function in the motor neurons. One potential mechanism for CA1's involvement in ALS pathology can be through the ER stress-response pathway.

Title: Compartmentalized motoneuron cultures reveal alterations in axonal mRNAs after TDP-43 depletion

Authors: *L. SAAL[1], M. BRIESE[1], S. KNEITZ[2], M. SENDTNER[1];
[1]Inst. for Clin. Neurobio., Wuerzburg, Germany; [2]Dept. of Physiological Chem. I, Theodor-Boveri-Institute for Biol. Sciences, Univ. of Wuerzburg, Wuerzburg, Germany

Abstract: Compartmentalized culture systems are ideal tools for studying local signaling mechanisms including differential RNA distribution in axonal and somatodendritic compartments of neurons. We developed a technique for culturing primary mouse motoneurons in microfluidic chambers to investigate changes in levels and distribution of axonal transcripts after TDP-43 depletion. Gradients of the brain derived neurotrophic factor (BDNF) were used to direct axon growth into a separate culture compartment. With this technique we studied the effects of TDP-43 suppression using lentiviral shRNA knockdown. After 7 DIV the RNA of the cellbody compartment and the axonal compartment was extracted, linearly amplified and hybridized on a 3'IVT Affymetrix Gene Chip® Mouse Array. Analysis of these microarray data shows a massive downregulation of specific axonal RNAs after TDP-43 depletion. Because the expression levels of these RNAs are unchanged in the somatodendritic compartment and only reduced in the axonal compartment, this indicates that, in addition to its well-characterized function in splicing, TDP-43 plays a role in axonal translocation of specific mRNAs, coding for proteins that are relevant for axonal and presynaptic differentiation and function. This is consistent with the observed phenotypes of shorter axons after TDP-43 knockdown in cultured motoneurons.

Title: Mutant SOD1 astrocytes display an accelerated aging phenotype in amyotrophic lateral sclerosis

Authors: *M. DAS, C. SVENDSEN;
RMI, Cedars Sinai Med. Ctr., Los Angeles, CA

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease characterized primarily by the death of motor neurons in the brain and spinal cord. However, ALS is not a cell autonomous disease; the glial microenvironment can significantly modulate motor neuron survival. Astrocytes with an ALS causing mutation such as in the protein superoxide dismutase I (SOD1) are detrimental to motor neuron survival. While many have embarked on the quest for the mechanism through which astrocyte-mediated toxicity occurs, the answer remains elusive.

The prevalence of amyotrophic lateral sclerosis (ALS) increases with age. However, the possible interaction between the normal degenerative aging process and the rapid cell loss in ALS has not been thoroughly investigated. Here, we find that compared to astrocytes from young rats, astrocytes from aged wildtype rats have a reduced ability to support motor neurons in culture. To investigate an explanation for age-related differences between astrocytes we look at cell senescence. Cellular senescence is a consequence of aging in many tissue types and the accumulation of these non-proliferating cells leads to tissue atrophy. We observe that aged astrocytes contain a higher proportion of senescent cells relative to young astrocytes. Surprisingly, we find that astrocytes from an ALS rat develop a large population of cells in a senescent state at younger age than wildtype rats. ALS astrocytes display a significantly higher proportion of senescent cells compared to an age-matched wildtype counterpart. These data suggest that a mechanism long associated with aging is amplified in the presence of toxic protein stress. Identifying the cellular changes during aging that influence neurodegenerative disease can help us gain insight into identifying new targets to combat ALS.

Glial-derived neurotrophic factor (GDNF) is a protein shown to directly promote motor neuron survival. Here, we show that GDNF can alter astrocyte gene expression. We find that exogenous addition of GDNF onto astrocytes can reduce p21 expression and decrease senescence associated cytokine secretion. Hence, we have found a novel method to modulate the environment of aged and SOD1 motor neurons.

Title: Targeting misfolded SOD1 as a therapy for ALS

Authors: *A. ISRAELSON[1], D. W. CLEVELAND[2];
[1]Ben Gurion Univ., Beer Sheva, Israel; [2]Ludwig Inst. for Cancer Res., La Jolla, CA

Abstract:
Amyotrophic lateral sclerosis (ALS) is a late-onset fatal neurodegenerative disease characterized by the loss of upper and lower motor neurons. The reason for the degeneration of motor neurons in ALS is still unknown. Mitochondria have been implicated as a possible target for toxicity by several studies reporting a range of dysfunctions and the toxic binding of misfolded SOD1 to mitochondrial targets. However, the mechanism by which mutant SOD1 associates with mitochondria specifically from affected tissues is still unknown. Preliminary data show that a cytosolic factor in unaffected tissues is responsible for preventing the accumulation of misfolded SOD1. Using mass spectrometry, this factor was identified as a multifunctional protein with activities as an intracellular chaperone. The factor directly inhibits mutant SOD1 binding to mitochondria and misfolded SOD1 is suppressed by increased expression of that chaperone in neuronal cells. Antisense oligonucleotide-mediated reduction of the newly identified chaperone in peripheral tissues of mutant SOD1-expressing rats induces misfolded SOD1, demonstrating that the endogenous chaperone suppresses misfolded SOD1 accumulation. In view of all the evidence to date, we believe that it is possible that the neurodegeneration observed in ALS is a result of a reduction or malfunction of specific chaperones, leading to accumulation and toxicity of misfolded SOD1. We suggest that finding these pathways and identifying this chaperone for misfolded SOD1 will make a positive contribution for the future development of ALS therapies.

Title: Evidence for a dying-forward process of ALS in the SOD1 rat

Authors: *G. M. THOMSEN[1], G. GOWING[1], P. AVALOS[1], J. LATTER[1], K. STAGGENBORG[1], R. PARADIS[1], M. CHEN[1], A. LIN[1], B. KASPAR[2], C. SVENDSEN[1]; [1]Cedars Sinai Med. Ctr., West Hollywood, CA; [2]Nationwide Children's Res. Institute, Ohio State Univ. Sch. of Med., Columbus, OH

Abstract: The mechanisms underlying the causality of motor neuron death in Amyotrophic Lateral Sclerosis (ALS) have yet to be elucidated. Conflicting reports exist in support of two main hypotheses: (i) The "dying-forward" hypothesis proposes that ALS is mainly a disorder of cortical motor neurons, which connect with anterior horn cells of the spinal cord mediating anterograde degeneration of these cells leading to muscle degeneration. (ii) The "dying-back" hypothesis proposes that ALS begins at the neuromuscular junction. These hypotheses are largely unexplored in the hSOD1(G93A) rat model of ALS. Here, we evaluated the degree and timing of degeneration in the cortex, spinal cord, distal (L5 ventral root) axons and muscle in pre-symptomatic, early symptomatic and endpoint SOD1 rats. We provide evidence that the degenerative process in SOD1 rats begins in upper motor neurons and not in the muscle, thereby supporting the "dying-forward" hypothesis of ALS. We found that the first sign of alterations in these rats occurred in the cortex whereby CTIP2+ corticospinal motor neurons in layer V were significantly smaller than those of wildtype controls. This occurred as early as 90 days of age, prior to the onset of symptoms. Spinal motor neuron degeneration was also first observed pre-symptomatically at p120, at which point total numbers of large ChAT+ neurons were significantly decreased. On the other hand, there were only minimal signs of distal axonal degeneration at p120 and nearly all (>95%) of neuromuscular junctions were still fully innervated at this time point. Significant denervation of muscle did not occur until the early symptomatic time point, at which point nearly 75% of NMJs had become denervated. We also injected pseudorabies virus, a retrograde tracer, into the gastrocnemius at various time points to examine the circuitry between muscle and cortex in SOD1 rats. After quantifying retrogradely labeled corticospinal motor neurons, we found that at p120, but not at p90, there were significantly fewer labeled cortical layer V neurons. Although neuromuscular junctions appear healthy at presymptomatic time points, this suggests that there is an early disconnect within the circuitry of SOD1 rats. Further analyses including examination of labeled spinal motor neurons are ongoing to determine the origin of this disconnect. Additionally, studies are underway to further test the dying-forward hypothesis in the SOD1 rat model using AAV9-siRNA to knock down SOD1 expression in the brain and spinal cord. Studies such as these will provide insight into the origin of degeneration of ALS in order to develop potential therapeutic approaches.

Title: TARDBP mutations associated with amyotrophic lateral sclerosis alter the efficiency of its own alternative splicing

Authors: T. KONNO, A. KOYAMA, M. KOYAMA, A. SUGAI, T. KATO, *T. ISHIHARA, M. NISHIZAWA, O. ONODERA;
Niigata Univ. Resource Br. For Brain Dis., Niigata, Japan

Abstract: Background: TAR DNA-binding protein 43 (TDP-43), encoded by TARDBP, is a major component of neuronal cytoplasmic inclusions, which are observed in affected neurons in patients with amyotrophic lateral sclerosis (ALS). To date ~40 mutations in TARDBP were identified in patients with ALS, and most of them located in exon 6, the last exon of TARDBP. It is known that TDP-43 regulates its own protein level through binding TARDBP pre-mRNA and introducing intra-exonic alternative splicing in exon 6, and produces splicing isoforms with a premature termination codon. They are supposed to be degraded by nonsense-mediated mRNA decay. Given the fact that the mutations in TARDBP are concentrated in exon 6, we speculate that the mutations affect the alternative splicing.
Object: To investigate whether mutations associated with ALS alter the efficiency of its own alternative splicing.
Materials and Methods: We generated minigenes containing wild-type and mutant (G295S, G298S, A315T, M337V, Q343R, G348C and A382T) TARDBP exon 6 with flanking intron sequence. Next, to assess the effect of mutations on cis-acting RNA sequence motifs, we transiently transfected these minigenes into HEK293T cells with or without wild-type TDP-43. In addition, to assess whether mutant TDP-43 cause mis-splicing of TARDBP pre-mRNA by acting as trans-acting factor, we transiently co-transfected mutant TDP-43 and wild-type minigene into HEK293T cells. We extracted RNA from cells at 48 hours after transfection. We conducted reverse-transcription polymerase chain reaction using minigene specific primers and

gel electrophoresis to evaluate the alternative splicing.
Results: Wild-type TDP-43 efficiently produced intra-exonic splicing isoforms from wild-type minigene. We found that wild-type TDP-43 less efficiently produced the splicing isoforms from some mutant minigenes than wild-type minigene. In contrast, mutant TDP-43 protein produced the splicing isoforms comparable to those of wild-type TDP-43.
Discussion: These results indicated that the mutations in TARDBP could alter the efficiency of the alternative splicing. The investigation of these findings in neuronal cells or the affected tissue from patients with ALS would be interesting.

Title: Alternative splicing or polyadenylation, which is the major mechanism for auto-regulation of TDP-43?

Authors: A. SUGAI, A. KOYAMA, T. KATO, T. KONNO, T. ISHIHARA, M. NISHIZAWA, *O. ONODERA;
Brain Res. Institute, Niig, Niigata, Japan

Abstract: Background: TAR DNA binding protein-43 (TDP-43), predominantly nuclear protein, plays a key role in pathogenesis of amyotrophic lateral sclerosis. Accumulating evidence suggest that TDP-43 levels in nucleus should be strictly regulated especially in central nervous system. TDP-43 is auto-regulated via binding to its own 3'UTR. Following mechanism of the auto-regulation, however, remains unclear.
Objective: To investigate the mechanism of TDP-43 auto-regulation.
Materials and Methods: Flp-In 293 cell lines stably expressing myc-tagged wild-type TDP-43 cDNA was used to investigate elevated TDP-43 effects on endogenous TDP-43 mRNA.

Minigene containing wild-type exon-6 of TDP-43, which includes TDP-43 binding region, was used to investigate depleted TDP-43 effects on the transcripts. In situ hybridization, northern blotting of polyA (+) RNA in cytoplasmic and nuclear extraction, and 3'-end qRT-PCR were performed to evaluate distribution and expression levels of each isoform of the transcripts.
Results: Northern blot analysis and qRT-PCR revealed that TDP-43 mRNA was alternatively polyadenylated. The levels of transcripts using distal polyadenylation sites were increased with increasing TDP-43 levels. In situ hybridization and northern blot analysis of RNA extracted from nucleus or cytoplasm showed that substantial amounts of TDP-43 mRNA with distal polyadenylation were located in nucleus. The increasing level of TDP-43 reduced its own mRNA from cytoplasm, whereas the TDP-43 mRNAs in nucleus with distal polyadenylation sites were unchanged. The mRNA with different polyadenylation sites, however, did not alter its stability. Northern blot analysis upon cycloheximide treatment showed shorter isoforms, excised two or three introns in exon-6. These isoforms fulfilled the criteria for nonsense-mediated mRNA decay (NMD).
Conclusion: Increasing TDP-43 undergo excision of intra-exonic introns, resulting in reduction of its own mRNA via NMD pathway. In addition, the amounts of TDP-43 altered the polyadenylation sites in combination with alternative splicing, which regulates intracellular distribution (nuclear or cytoplasm) of the mRNA. These mechanisms are collaboratively involved in the auto-regulation of TDP-43.

Title: A stem cell model of the motor circuit reveals distinct requirements of SMN for motor neuron survival and function

Authors: *C. M. SIMON, A. JANAS, F. LOTTI, L. PELLIZZONI, G. MENTIS;
Col. of Physicians and Surgeons, Motor Neuron Ctr., New York, NY

Abstract: Spinal muscular atrophy (SMA) is a motor neuron disease caused by deficiency in the ubiquitously expressed survival motor neuron (SMN) protein. Although a hallmark of the disease is the death of motor neurons, studies from animal models revealed that neuronal circuit perturbations are important determinants of SMA pathogenesis that precede motor neuron loss. It is currently unknown if motor neuron death and circuit dysfunction are linked events induced by SMN deficiency. To address this, we have generated mouse ES (Hb9::GFP) cell lines with regulated RNAi knockdown of endogenous SMN and established a simplified *in vitro* model of motor circuits based on the use of ES-derived motor neurons (MNs) and interneurons (INTs). MNs differentiated from ES (Hb9::GFP) cells express GFP under the control of the MN-specific Hb9 promoter and their survival over time was measured using whole-well automated imaging in 96 well format. This time-course analysis revealed significantly decreased survival of SMN-deficient MNs relative to controls. To investigate whether MN death induced by SMN deficiency was a cell autonomous process, we purified ES-MNs by FACS. We found that the rate of death of purified SMN-deficient ES-MNs does not significantly differ from that of SMN-deficient MNs co-cultured with INTs. In addition, SMN deficiency leads to preferential loss of MNs compared to INTs.
ES-derived INTs are both excitatory (VGluT2,3) and inhibitory (VGAT, GlyT2) and form synapses onto the soma and dendrites of MNs. To study SMN requirement for motor neuron function in our *in vitro* motor circuit, we employed intracellular patch clamp recordings. SMN-deficient MNs exhibited an increase in the passive membrane properties compared to MNs with normal SMN levels. To determine if the hyperexcitability of SMN-deficient MNs was cell-autonomous, we recorded from FACS purified ES-MNs and found that SMN deficiency had no effects on the intrinsic properties of MNs cultured in isolation. To quantify MN output, we measured the spontaneous firing frequency. SMN deficiency caused a significant reduction in the firing frequency of MNs co-cultured with INTs compared to normal controls.
These results show that neuronal death induced by SMN deficiency occurs via cell-autonomous mechanisms and preferentially affects MNs. In contrast, they reveal a non-cell autonomous origin for the SMN-dependent changes in the spontaneous activity and intrinsic excitability of MNs. Collectively, our study suggests that dysfunction and death of motor neurons are distinct events that occur downstream of SMN deficiency as a result of differential effects in specific neuronal types.

Title: Astrocytes harboring Amyotrophic Lateral Sclerosis-causative mutations alter ABC drug efflux transporters at the endothelial cell layer

Authors: *M. R. JABLONSKI, D. A. JACOB, P. PASINELLI, D. TROTTI;
Thomas Jefferson Univ., PHILADELPHIA, PA

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a slowly progressing neurodegenerative disease, characterized by motor neuron degeneration. ALS is a non-cell-autonomous disease with astrocytes contributing to toxicity and selective loss of motor neurons. The blood-brain barrier (BBB) is formed by endothelial cells in association with pericytes and astrocytes, forming the neurovascular unit. Astrocytic end-feet encapsulate approximately 90% of endothelial cells and maintain homeostasis of the barrier. ABC drug efflux transporters, highly localized in endothelial cells, prevent a wide range of neurotoxicants and therapeutics from entering the CNS. We recently reported a disease-driven increase in expression and function of P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP) in ALS mouse spinal cord capillaries and expression increases in human spinal cord tissue (Jablonski et al. 2012; Neurobiol Dis), suggesting these transporters could mediate ALS pharmacoresistance. Due to the toxic contribution by astrocytes in ALS, we hypothesized that toxic astrocytes impart increases in ABC transporters in endothelial cells, leading to a decrease in bioavailability of therapeutics in the CNS. To examine this hypothesis, we implemented a co-culture system whereby primary cultured mouse brain endothelial cells or the mouse brain endothelioma cell line, bEnd.3, were plated on a transwell above a layer of primary mouse astrocytes. Astrocytes were either oxidatively stressed, indicative of a potential mechanism of neurodegeneration in ALS, or infected with virus expressing wild-type or an ALS-causative mutant (G93A) superoxide dismutase-1 (SOD-1). Oxidatively stressed astrocytes increased P-gp expression dose-dependently in bEnd.3 cells. SOD1-G93A virus-treated astrocytes significantly increased P-gp expression levels in bEnd.3 cells and primary cultured endothelial cells compared to astrocytes treated with wild-type SOD1 virus. NFkB inhibition (SN50) in endothelial cells and bEnd.3 cells prevented the endothelial P-gp expression increases seen with oxidatively stressed or SOD1-G93A-containing astrocytes. This project is an important step in understanding drug efflux transporter regulation in ALS.

Title: SMA skeletal muscles in primary cell culture have normal morphology, survival, growth, and response to DNA damage

Authors: *S. FAYZULLINA, L. J. MARTIN;
Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: We previously showed that spinal muscular atrophy (SMA) mice exhibit skeletal muscle DNA damage and cell death before major spinal cord motor neuron cell body and axon degeneration. We investigated whether the observed DNA damage is due to faulty DNA repair in SMA skeletal muscle. Using a mouse model of SMA (Hsieh-Li et al. 2000), we established primary myoblast cultures from the skeletal muscles of SMA mice and control littermates. Myoblast cultures were then differentiated into myotubes. Myotube differentiation and growth was assessed by measuring myotube length and counting myonuclei. DNA damage was induced by gamma-irradiation, etoposide, and methane methylsulfonate (MMS). DNA damage was detected by the comet assay. DNA damage response was assessed by phospho-p53 (S15) and γH2AX immunofluorescence.
SMA mice had smaller muscle mass than littermate control mice at harvest, but cultures seeded at equal cell density resulted in myotube density similar to control myotubes. Myotubes cultured from SMA mice at P5 had similar morphology, multinucleation, and length, compared with control myotubes. Gamma-irradiation (5 Gy) induced comparable levels of DNA damage in SMA and control myotubes, as indicated by the distribution of comet scores. After a 1 hour recovery period, both SMA and control myotubes repaired most of the induced damage. Etoposide treatment (10 μM for 1 hour) yielded similar results. MMS (100 μg/mL) induced similar DNA damage in SMA and control myotubes. SMA myotubes were not more sensitive to a low dose of MMS (1 μg/mL) than controls. In both SMA and control myotubes, without induction of DNA damage, we observed discrete, colocalized foci of γH2AX and phospho-p53 in myotube nuclei. DNA damage, induced by either irradiation or etoposide, caused dispersal of

foci within the nucleus. After a 1 hour recovery period, the nuclear foci re-assembled in most myotube nuclei. Both dispersion and re-assembly of nuclear foci upon recovery were similar in SMA and control myotubes.
We observed that primary skeletal muscle cells cultured from SMA mice exhibit myotube formation and growth comparable to control cultures. SMA and control myotubes have similar sensitivity to DNA damage, induced by either irradiation or chemical agents. SMA myotubes exhibit a normal response to DNA damage and functional DNA repair. These observations indicate that the DNA damage and cell death observed in skeletal muscle of SMA mice is unlikely to be due to faulty autonomous DNA repair mechanisms or differentiation. Our observations indicate that the marked prenatal DNA damage accumulation in skeletal muscle of SMA mice is likely a consequence, rather than a primary cause, of myocyte cell death.

Title: Non-cell autonomous mechanisms induce hyperexcitability of motor neurons in a mouse model of spinal muscular atrophy

Authors: *E. FLETCHER, G. Z. MENTIS;
The Ctr. for Motor Neuron Biol. and Dis., Columbia Univ., New York, NY

Abstract: Spinal muscular atrophy (SMA) is a severe neurodegenerative disease caused by reduced levels of the survival motor neuron (SMN) protein. The hallmarks of SMA are loss of

motor neurons, muscle atrophy and abnormal postural reflexes. However, the mechanisms by which a reduction in SMN protein leads to selective motor deficits and muscle weakness are poorly understood. Using the SMA-Δ7 mouse model, we have previously shown that sensory-motor circuit dysfunction occurs early in development and precedes motor neuron loss in the course of the disease. At post-natal day 4 (P4), L1-L2 lumbar motor neurons innervating proximal muscles are abnormally hyperexcitable and exhibit reduced stretch reflexes compared with L5 motor neurons innervating distal hindlimb muscles which are affected at a later stage. To address whether this hyperexcitability is due to premotor synaptic dysfunction or due to SMN deficiency *per se* in motor neurons, we investigated the intrinsic properties of both: i) L1-L3 motor neurons at P2 and ii) L5 motor neurons at P4.

We employed the intact *in vitro* spinal cord preparation from age-matched wild type (wt) and SMA-Δ7 mutant mice. We measured the passive membrane properties of input resistance (R_{IN}) and time constant (τ) as well as the rheobase current using whole-cell patch clamp recordings from motor neurons, identified by ventral root antidromic stimulation. Our preliminary results reveal that L1-L3 SMA motor neurons at P2 were significantly hyperexcitable compared with their wt counterparts for all three parameters tested (R_{IN}: 67.9±12.5MΩ in wt, n=8, and 171.0±28.7 MΩ in SMA, n=6; $P<0.01$, t-test. τ: 10.1±1.2ms in wt and 17.8±2.5ms in SMA, $P<0.001$, t-test). At the same time, the monosynaptically-evoked EPSPs following proprioceptive fibers stimulation revealed a significant reduction. The intrinsic properties of L5 motor neurons at P4 however, did not reveal any significant alterations for the same intrinsic membrane properties. As expected, the monosynaptic EPSPs were similar between wt and SMA mutants in L5 motor neurons at P4.

These findings indicate that SMN deficiency alters the intrinsic excitability of SMA motor neurons through non-cell autonomous mechanisms resulting from spinal circuit dysfunction, consistent with SMA being a disease of motor circuits.

Title: Dysregulation of atypical PKC and Ryk in a mouse model of amyotrophic lateral sclerosis

Authors: *A. TURY, K. TOLENTINO, A. FENSTERMAKER, R. MCRAE, Y. ZOU;
Div. of Biol. Sciences, Section of Neurobio., UCSD, La Jolla, CA

Abstract: Amyotrophic lateral sclerosis (ALS) is a devastative neurodegenerative disease characterized by the degeneration of lower and upper motor neurons, with no available cure. The primary causes of motor neuron degeneration are still unknown. Increasing evidence indicates that Wnt signaling is dysregulated in neurodegenerative diseases, including ALS. In this study, we focused on two non-canonical Wnt signaling components, atypical PKC (aPKC) and Ryk. aPKC mediates Wnt signaling to regulate growth cone guidance, axon differentiation and cell death/survival. Ryk is a repulsive receptor for Wnts that is re-expressed and inhibits regeneration after spinal cord injury and our preliminary results suggest that Ryk reduces neuronal cell death triggered by loss of Frizzled 3. We found that aPKC expression was increased in motor neurons of the ventral lumbar spinal cord in a mouse model of ALS (SOD1-G93A) at early and late stages of the disease compared to SOD1-WT mice. aPKC upregulation may either contribute to the disease or may be a failing attempt to protect motor neurons from degeneration. We found that aPKC activity measured by the level of autophosphorylation of aPKC by western blotting was reduced. The ratio of total aPKC was increased in the detergent insoluble fraction in SOD1-G93A mice and aPKC colocalized with SOD1 aggregates. In addition, we found that aPKC aggregates increased in the ventral horn of the spinal cord with disease progression. These results suggest that aPKC may be trapped in mutant SOD1 aggregates and not be able to function properly to protect motor neurons from death. We also found that Ryk expression was increased in the motor neurons and the ventral white matter in the ventral lumbar spinal cord of mutant SOD1 mice at different stages, with a peak of increase in motor neurons at early stage. One hypothesis is that Ryk might be involved in the early events that triggers axonal and motor neuron degeneration in the spinal cord of ALS mice. These studies suggest that Wnt/aPKC and Wnt/Ryk signaling may be potential targets for treatment of ALS.

Title: Reduction of U11/U12 small nuclear ribonucleoprotein in amyotrophic lateral sclerosis

Authors: T. ISHIHARA, T. KATO, A. SHIGA, *A. YOKOSEKI, A. KAKITA, M. NISHIZAWA, H. TAKAHASHI, O. ONODERA;
Niigata Univ., Niigata, Japan

Abstract: OBJECTIVE:To investigate 1) whether the repertoires of U11/U12 spliceosome alter in affected neuronal tissues with amyotrophic lateral sclerosis (ALS), 2) whether pre-mRNA splicing associates with U11/U12 spliceosome alters in ALS affected tissues.
INTRODUCTION: TAR-DNA Binding Protein 43kDa (TDP-43) has crucial role in the pathogenesis of ALS. TDP-43 is one of the heterogeneous nuclear ribonucleoproteins and co-localizes with GEM, which is one of the nuclear bodies composed chiefly of survival of motor neurons (SMN). SMN is a causative protein for spinal muscular atrophy, an infantile onset motor neuron disease. SMN plays an important role in maturation of snRNAs which are components of spliceosome. Spliceosome is the machinery that carries out pre-mRNA splicing, and is classified into two types; major (U1, U2, U4, U5 and U6) and the minor (U11, U12, U5, U4atac and U6atac) spliceosomes. Depletion of SMN alters the repertoires of snRNAs by cell and tissue-type specific manner, particularly reduction of U11/U12 snRNAs in spinal cord (Zhang et al. cell.2008). We have found that U12 snRNA decreased in affected tissues with ALS (Ishihara, reported in SFN 2012). However it is unclear whether the reduction of the snRNAs alters the amounts and function of minor spliceosome.
METHODS: Spliceosome is composed of snRNAs and associated proteins complex, small nuclear ribonucletide protein (snRNP). Thus we investigated the amount of U11/12 type spliceosome in spinal motor neurons with ALS patients and controls (n=4) by immunofluorescent staining with antibody to snRNP 59 kDa, which is a component of minor spliceosome. Quantitative real-time RT-PCR of snRNAs and splicing efficiency of pre-mRNA were performed with RNA from cultured cells and neuronal tissues (spinal cord, motor cortex and cerebellum as tissues with or without TDP-43 pathology) from ALS patients (n=7-10) and control individuals (n=9-10). Total RNA was extracted using mirVana miRNA isolation kit (Ambion).
RESULTS: The fluorescence intensity of snRNP 59K was decreased to 39% in spinal motor neuron with ALS compared with control. The level of mRNA in which minor spliceosome dependent intron was included significantly increased in TDP-43 depleted U-87 MG cells (218%), and the same results were obtained in the motor cortex with ALS but not in spinal cord and cerebellum.
DISCUSSION: The decreased amounts of snRNP 59K indicate that the reduction of U12 snRNA reduces the level of minor spliceosome. In addition, some minor spliceosome dependent introns were retained in affected tissue with ALS. Our results suggest that decreasing the function of minor spliceosome may underline the molecular pathogenesis of ALS.

Title: Plasma biomarker panels predict prognosis in amyotrophic lateral sclerosis

Authors: *X. W. SU[1], Z. SIMMONS[2], R. M. MITCHELL[1], H. E. STEPHENS[2], J. R. CONNOR[1];
[1]Neurosurg., [2]Neurol., Penn State Col. of Med., Hershey, PA

Abstract: Background: It is difficult to predict prognosis in ALS. Although median survival is 2-4 years, survival ranges from months to decades. This uncertainty complicates clinical management and outcomes assessment associated with treatment trials.
Objectives: To identify panels of plasma cytokines, trophic factors and metabolites with prognostic value in ALS, and to use novel multivariate modeling strategies incorporating these panels to predict disease prognosis.
Methods: An IRB-approved, retrospective analysis of plasma from 26 sporadic ALS patients seen at a university-based multidisciplinary ALS clinic was conducted. Plasma was analyzed with multiplex and ELISA assays as well as clinical laboratory procedures. Multiplex and ELISA assays measured levels of 27 and 8 biomarkers, respectively. Gender, H63D HFE status and site of onset were included as categorical variables. Clinical measures, including disease duration, rates of decline in forced vital capacity (FVC) and ALS Functional Rating Scale-Revised (ALSFRS-R) scores, and time to non-invasive ventilation (NIV), served as dependent variables. Statistical modeling used hierarchal forward, main effects only multivariate regression with stepwise switching. Goodness-of-fit validation and power analyses were performed. Individual subject-level 95% confidence bands for predictions were constructed.
Results: Models for disease duration, rates of decline in FVC and ALSFRS-R scores, and time to NIV incorporated six, four, three, and five predictive biomarkers to achieve R-squared values of

0.820, 0.723, 0.640 and 0.913, respectively. Inflammatory cytokines, including select interleukins (IL), and indicators of iron metabolism, including transferrin and transferrin saturation, had predictive value. IL-1β, eotaxin and transferrin were significant predictors in multiple models. After classification of disease duration into categories, all predictions were within one level of actual outcome, with 10 out of 11 patients with slow progression (survival more than four years) predicted to have less aggressive disease. Select biomarkers were consistent with previous reports, including IL-1β and RANTES as negative predictors, and granulocyte-colony stimulating factor as a positive predictor. Bulbar onset was associated with higher rates of decline in FVC, as expected given the difficulty for these patients to complete FVC measurements, highlighting the validity of results.
Conclusions: These results support plasma biomarker-based predictive modeling of ALS prognosis, and provide a rationale for unbiased biomarker discovery and longitudinal follow-up in larger patient populations.

Title: Thr175 phosphorylation regulates GSK3β activity and tau fibril formation *In vitro*

Authors: A. MOSZCZYNSKI[1], M. GOHAR[1], K. VOLKENING[1], *M. J. STRONG[2]; [1]Mol. Med., Robarts Res. Inst., London, ON, Canada; [2]London Hlth. Sci. Ctr. - UH, London, ON, Canada

Abstract: Background: Amyotrophic lateral sclerosis (ALS) is an untreatable, progressive neurodegenerative disorder defined by upper and lower motor neuron loss. Up to half of all ALS patients develop cognitive impairment (ALSci) which we have shown to be characterized by pathological fibril formation of microtubule associated protein tau. Phosphorylation of Thr175 (pThr175) has been observed specifically in ALSci, and can induce fibril formation and increased cell death in vitro. Threonine175 phosphorylation has been linked to increased GSK3β activation in vivo. In this study, we have examined whether the presence of pThr175 leads directly to the activation of GSK3β as a determinant of pathological fibril formation.
Methods: HEK293T cells were transiently transfected with either wild-type (wt) or

pseudophosphorylated (Thr175Asp) GFP-tagged 2N4R tau, or with GFP-tagged 2N4R tau in which phosphorylation at Thr175 is inhibited (Thr175Ala). Activation of GSK3β was examined by western blotting for phospho-GSK3β(Tyr216) and the effect of a panel of GSK3β inhibitors characterized with respect to their ability to inhibit GSK3β activation and cytotoxicity.
Results: Four GSK3β inhibitors were examined for toxicity at their IC50 values: Lithium chloride (LiCl; IC50 5mM) showed a 35% reduction in cell survival while AR-A014418 (100nM), Tideglusib (60nM) and TWS119 (30nM) did not show reductions in survival at their respective IC50. Both the empty vector and Thr175Ala transfected cells demonstrated similar levels of endogenous GSK3β activation, while wt-tau demonstrated a significant up-regulation of GSK3β activation. Thr175Asp transfected cells demonstrated a significant up-regulation of GSK3β activity. LiCl administration reduced GSK3β activation by 50% in wild type tau expressing cells.
Conclusions: These preliminary studies demonstrate the ability of tau to induce the activation of GSK3β in HEK293T cells. This activation appears to be dependent in part on the presence of pThr175 and can be inhibited with specific inhibitors of GSK3β . We hypothesize that Thr175 phosphorylation activates GSK3β, leading to further downstream processes culminating in tau pathology. This suggests a potential avenue of therapeutic intervention for the cognitive dysfunction of ALS.

Title: Plastin acts a genetic modifier of neurodegenerative diseases

Authors: *M. WALSH, E. WINGROVE, A. HART;
Neurosci., Brown Univ., Providence, RI

Abstract: Spinal Muscular Atrophy (SMA) is a neurodegenerative disease caused by low levels of the Survival Motor Neuron (SMN) protein. Plastin 3 (PLS3) was identified as a human genetic modifier for SMA (Oprea *et al.*, 2008). This study reported that over-expression of PLS3 ameliorates symptoms in less severe SMA cases and PLS3 protein is in a complex with SMN in

neuronal tissues. PLS3 is an actin-bundling protein and the mechanism of SMA suppression remains unclear. Our objective is to understand the interaction between PLS3 and SMN in SMA, and to determine if PLS3 is a cross-disease modifier. Using the model system *Caenorhabditis elegans*, we examine PLS3 as a cross-species modifier of neurodegenerative disease and probe pathways involved in PLS3 suppression of SMA.
Animals with decreased levels of *C. elegans Ce*SMN-1 have neuromuscular defects in locomotion and pharyngeal pumping assays. We find that 2-fold over-expression of PLS3 (PLS3 OE) rescues neuromuscular defects in the SMA model. Ubiquitous PLS3 OE using either human or *C. elegans* plastin ameliorates the neuromuscular defects in *Cesmn-1* deficient animals. Neuron PLS3 levels are most critical as neuronal, but not muscle, expression of PLS3 rescues at high copy number. We also determined if PLS3 OE could rescue the neuromuscular defects in established *C. elegans* ALS and polyglutamine disease models. We find that PLS3 OE suppresses many of the behavioral defects in these models, demonstrating that PLS3 is a cross-disease modifier in *C. elegans*. To understand the mechanistic interaction between PLS3 and SMN, we are testing candidate genes from a list of proteins that pull-down with both SMN and PLS3 (Guruharsha et al., 2011). Thus far, we have identified several proteins/genes that act as genetic modifiers of both PLS3 OE and *Ce*SMN1 deficient animals. Further molecular and biochemical assessment is on going to determine which gene/proteins play critical roles in PLS3 suppression of SMN loss of function defects, which causes SMA.

Title: Protein expression with implications for selective vulnerability in motor neuron disorders

Authors: *L. H. COMLEY, I. ALLODI, S. NICHTERWITZ, A. BERGSTRAND, E. HEDLUND;
Dept. of Neurosci., Karolinska Institutet, Stockholm, Sweden

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder, characterised by selective degeneration of the somatic motor neurons, leading to muscle wasting. Distinct populations of motor neurons show differential vulnerability to degeneration in ALS; whilst those in the oculomotor nucleus, controlling eye-movements, are generally spared, motor neurons in the hypoglossal nucleus and spinal cord are vulnerable to degeneration. To understand the reasons underlying this differential vulnerability we have analysed the global gene expression profiles of vulnerable and spared motor neurons, and identified multiple genes that show a restricted expression in vulnerable motor neurons of the hypoglossal nucleus and spinal cord. We are now analysing the expression levels of candidate genes from this screen in human brain and spinal cord tissue from non-demented controls and ALS patients. The genes being evaluated include; peripherin, a neurofilament protein, overexpression of which causes ALS-like motor neuron degeneration; dynein, a retrograde axonal transporter, mutations in which have also been shown to cause ALS-like pathology; and GABA receptor alpha2, which has a role in modulating motor neuron excitability. We anticipate that knock-down of vulnerability transcripts could confer protection to susceptible motor neurons, and provide new targets for treatments for ALS.

Title: A protein signature of human motor neuron resistance in Amyotrophic Lateral Sclerosis

Authors: *S. NICHTERWITZ, L. H. COMLEY, I. ALLODI, A. BERGSTRAND, E. HEDLUND;
Dept. of Neurosci., Karolinska Institutet, Stockholm, Sweden

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal disorder characterised by the selective and progressive degeneration of somatic motor neurons. However, not all somatic motor neurons degenerate in ALS; certain groups of motor neurons, including those in the oculomotor (OM) nucleus (controlling eye movements) are spared. The reasons for this differential vulnerability among motor neurons remain largely unknown, and multiple factors are expected to be involved. Identification of mechanisms of differential motor neuron vulnerability may lead to therapies preventing the progressive loss of motor neurons in ALS.
Using a global gene expression analysis we have previously identified multiple genes that show a restricted expression in either resistant or vulnerable motor neurons in the rodent. Interestingly, several of the identified OM-restricted proteins, including parvalbumin, insulin-like growth factor II (IGF-II) and guanine deaminase (GDA), can protect vulnerable motor neurons from ALS like toxicity. We are now analysing candidate genes in human brain and spinal cord tissue from non-demented controls and ALS patients to evaluate their possible importance for human motor neuron susceptibility. Multiple genes with potential OM-restricted expression, including early growth response 1 (Egr1), guanylate cyclase 1a3 (Gucy1a3), IGF-II, GDA and Gabra1 are being evaluated. We anticipate that particular transcripts, with a preferential expression in resistant oculomotor motor neurons could be modulated to induce resistance to degeneration.

Title: Neuromuscular alterations following unilateral isometric strength training in SOD1-G93A rats

Authors: K. G. STANFORD[1], J. D. ODUM[1], A. D. RORIE[1], R. S. ROGERS[1], J. L. WHEATLEY[1], P. C. GEIGER[1], H. NISHIMUNE[2], *J. A. STANFORD[1];

Abstract: Muscle use and exercise have long been implicated in the etiology and site of onset of Amyotrophic Lateral Sclerosis (ALS). This hypothesis is controversial because it is very difficult to test in humans. Preclinically, confounds inherent to conventional rodent-basedexercise protocols have also complicated interpretation. Recent studies indicate that increased AMP Kinase (AMPK) activity may worsen motor deficits in ALS. This supports the muscle use hypothesis because AMPK is activated (phosphorylated; pAMPK) during exercise. We trained SOD1-G93A rats to perform a unilateral isometric strength training task to determine if muscle strength training increases pAMPK levels and affects denervation in the trained forelimb muscles. After testing rats daily for approximately 2 months (until ~5.5 months of age), trained and untrained forelimb muscles were harvested for AMPK and pAMPK protein analysis, and for neuromuscular junction (NMJ) innervation. Our results revealed that even at endstage, SOD1-G93A rats maintained force output, although forelimb tremor was increased. Strength training increased pAMPK and protected against NMJ denvervation in trained muscles. Effects of training on proteins related to other functions (glucose transport, autophagy) were also analyzed. These results are the first to demonstrate robust neuroprotective effects of non-aerobic resistance training in ALS. They also suggest that AMPK activation may have a beneficial role in ameliorating denervation in ALS, and cast doubt on previous studies indicating a detrimental effect of AMPK activation in ALS.

Abstract: Amyotrophic lateral sclerosis (ALS) is an adult onset neurodegenerative disease characterized by motoneurons (MNs) loss. However, spinal sensory afferents could be vulnerable as well [1,2]. Anatomical changes of the sensory ascending pathways, described using spinal magnetic resonance imaging (MRI) in recently-diagnosed ALS patients without sensory signs [3], further support this hypothesis. Yet, functional evidence is still lacking. In the present study we tested if the anatomical changes previously reported were accompanied by an altered excitability of the sensory feedback, at spinal and cortical level.
We combined spinal MRI and electrophysiological studies, in 18 ALS patients and 14 healthy subjects. Spinal MRI was done as in [3]. MRI metrics were measured at cervical levels in the lateral (motor tracts) and dorsal regions (sensory tracts). For the electrophysiology, median and ulnar nerves were stimulated electrically to activate group Ia fibers from hand-muscle (clinically altered). The subsequent somatosensory evoked potentials (SEPs) were recorded. Motor evoked potentials (MEP) were elicited in triceps brachii (clinically healthy) by transcranial magnetic stimulation (TMS) over the primary motor cortex. MEP recruitment curves were measured and MEP was conditioned by the peripheral nerve stimulations to assess the group Ia monosynaptic facilitation onto triceps' spinal MNs.
In patients, fractional anisotropy (FA) decreased in the dorsal region. In the lateral regions, FA tended to decrease while radial and mean diffusivity increased. Magnetization transfer ratio was unchanged whatever the region. The cortical SEPs' latency was unchanged but their amplitude

tended to decrease in patients. The peripheral component's amplitude (at Erb point) was reduced for both nerves. MEP recruitment curves were right-shifted in patients, with no other change, yet the maximal MEP tended to increase. This suggests an infra-clinical alteration of the cortico-motoneuronal pathway controlling the triceps. Both median- and ulnar-induced MEP facilitation tended to increase in patients. Only ulnar-effect was significant.
Though preliminary, our results suggest that early anatomical and physiological changes of the sensory feedback could occur in ALS patients. Further investigation is needed to confirm both MRI and electrophysiological results. Increased excitation onto the spinal MNs would contribute to their hyperexcitability, disturbing their homeostasis, and thus participate to the neurodegenerative process.

Title: Calcitonin gene-related peptide signaling influences motor symptom onset and disease progression in the superoxide dismutase 1 (G93A) mouse model of amyotrophic lateral sclerosis

Authors: *C. RINGER[1], K. TSUJIKAWA[2], E. WEIHE[1], B. SCHÜTZ[1];
[1]Mol. Neurosci., Philipps-Universität Marburg, Marburg, Germany; [2]Lab. of Mol. and Cell. Physiol., Osaka Univ., Osaka, Japan

Abstract: Amyotrophic lateral sclerosis (ALS) is a lethal neurodegenerative disease affecting predominantly motor neurons in the brainstem and spinal cord, resulting in progressive paralysis and finally death. Although the exact mechanisms causing motor neuron degeneration are not fully understood, neuroinflammation contributes to disease initiation and progression. Recently, we have shown that alterations in the sub-cellular distribution of the β isoform of calcitonin gene-related peptide (CGRP) in motor neurons precede astrogliosis (Ringer et. al., 2009) and that CGRP expression levels predict motor neuron vulnerability (Ringer et al., 2012) in the

superoxide dismutase 1 (SOD1-G93A) mouse model of ALS.
To further elucidate the possible pathogenic role of CGRP on ALS disease progression, we crossbred SOD1 mice with mice depleted of the CGRP-specific receptor component receptor activity-modifying protein 1 (RAMP1), and monitored clinical and histological symptom development and progression under presence and absence of functional CGRP signaling. SOD1:RAMP1-/- mice showed an earlier onset of hind limb motor deficits compared to SOD1:RAMP1+/+ mice (56 ± 30 days vs. 92 ± 20 days), while overall survival was similar (median 142 days vs. 137 days). On the cellular level, motor neuron degeneration in the lumbar aspect of the spinal cord started earlier in SOD1:RAMP1-/- mice when compared to SOD1:RAMP1+/+ mice, but was followed by decelerated motor neuron loss throughout disease progression. In addition, morphological activations of astrocytes and microglia, and lymphocyte infiltration were attenuated in SOD1:RAMP1-/- mice, both in pre-symptomatic, early symptomatic, and end-stage when compared to SOD1:RAMP1+/+ mice.
The observed effects under suppression of CGRP signaling in SOD1 mice suggest in turn that the secretion of CGRP by motor neurons is neuroprotective predominantly at disease-onset, possibly through stimulation of a protective neuro-inflammatory milieu. In contrast, CGRP signaling on glia at later stages furthers disease progression by promoting chronic neurodestructive neuroinflammation.

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder characterized by progressive loss of motor neurons (MNs) and astrogliosis. Several evidences suggest that the vulnerability of MNs is not cell-autonomous. Namely, factors secreted by activated astrocytes might contribute to MN degeneration and therefore their identification is important to develop new therapeutic strategies aimed at slowing disease progression and increasing survival of ALS patients. We focused on endothelin-1 (ET-1), a peptide which is strongly up-regulated in reactive astrocytes under different pathological conditions. ET-1 mRNA has been found to be up-regulated in the cortex of ALS patients. Furthermore, an increase in ET-1 levels in the CNS has been reported following spinal cord injury, a condition characterized by an extensive reactive gliosis.

We performed immunohistochemistry experiments in the G93A mouse model of ALS and in the spinal cord of ALS patients and revealed that ET-1 is strongly expressed in reactive astrocytes in both mouse and human specimens. To study a possible role of ET-1 on MN degeneration we used mixed spinal cord cultures enriched in reactive astrocytes and treated them with increasing concentrations of ET-1 for different length of time (8-72 hours). We chose an exposure of ET-1 (100-200 nM) for 48 hours, which resulted consistently in the death of 40-50% of MNs and 20% of other neuronal cells, whilst it did not exert any effect on astrocytes as revealed by immunocytochemistry and Western blotting analysis with SMI32, anti-MAP2 and anti-GFAP antibodies. ET-1 acts on both ET-A and ET-B receptors. ET-1 effect was mimicked by ET-3 (100 nM) and sarafotoxin S6C (10 nM), two selective agonists of ET-B receptors, and was not additive with that of ET-3 suggesting the involvement of ET-B receptors. Surprisingly, however, the ET-1 effect was only slightly reversed by the ET-A receptor antagonist BQ123 (2 uM), but was not affected by the ET-B receptor antagonist BQ788 (200 nM-2 uM), suggesting an atypical pharmacological profile of the receptors responsible for the observed ET-1 toxicity. ET-1 effect was not reversed by the ionotropic glutamate receptor AMPA antagonist GYKI 52466 (20 uM), suggesting that it is not caused by an increased glutamate release. Conversely, a 48 hour ET-1 treatment increased MN death induced by the acute exposure to AMPA (50 uM). Importantly, ET-1 did not induce MN death when administered on cell cultures treated with AraC (5 uM) or grown in a serum-free medium that did not favour astrocytes proliferation.

Overall these data suggest that ET-1 may contribute to MN degeneration in ALS through a mechanism mediated by reactive astrocytes.

Title: Chronic infusion of 4-aminopyridine in the spinal cord *In vivo* induces motor alterations but no neurodegeneration

Authors: R. LAZO-GÓMEZ, *R. TAPIA;
División de Neurociencias, Univ. Nacional Autonoma De Mexico, Mexico City DF, Mexico

Abstract: Amyotrophic lateral sclerosis is a devastating neurodegenerative disorder characterized by motor neuron (MN) death and paralysis. There is evidence that glutamate-mediated excitotoxicity may participate in MN death (Exp. Opin. Ther. Targets 11: 1415; 2007). On this base, we designed a model of chronic spinal MN neurodegeneration in vivo through the infusion of AMPA directly into the lumbar spinal cord of rats, using osmotic minipumps. Such chronic activation of AMPA receptors produces MN degeneration and paralysis of the hindlimbs 3-6 days after the beginning of AMPA infusion (J. Neuropathol. Exp. Neurol. 66: 913; 2007). We have now studied the effect of increasing endogenous glutamate by means of the infusion of 4-aminopyridine (4-AP), a K+-channel blocker that stimulates glutamate release. 4-AP [35 mM] was infused during 15 days, and motor changes were measured in the rotarod test and the paw grip endurance test (PGE).The number of MNs was assessed by histological observations and ChAT immunohistochemistry. One day after the beginning of 4-AP infusion the animals showed intermittent fasciculations in both hindlimbs and a significant decrease in the rotarod performance, but no alterations in the PGE test; these changes lasted 4-6 days and then gradually disappeared. However, quantitative histological observations showed that the number of healthy MN was normal. The motor alterations observed suggested MN hyperexcitation, possibly mediated by endogenous glutamate, so we tested if NMDA receptors could be involved by co-infusing MK-801 [1 mM] with 4-AP. In both motor tests, rats showed normal behavior, similar to that of control rats, and no significant changes were observed histologically. Since the neurotransmitter release induced by 4-AP is not specific for glutamate but may also affect GABA, which could be inhibiting the hyperexcitation and thus preventing MN death, we infused bicuculline [10 mM] (BIC) alone or in combination with 4AP. In the BIC + 4-AP group,

fasciculations were more frequent and intense, but the deficit in the rotarod test was similar to that after 4-AP alone, and again no MN degeneration was observed. On the other hand, BIC infusion alone produced compulsive scratching of the ipsilateral hindlimb and a significant loss of MN. We conclude that the hyperexcitation produced by 4-AP is probably due to NMDA receptor activation by the increased release of endogenous glutamate. This hyperexcitation was not enough for inducing MN death, due possibly to an increased inhibitory effect of GABAergic synapses.

Abstract: Alterations in RNA metabolism have been shown in ALS opening new research perspectives on its pathogenesis (Strong 2010). In this context, we have already demonstrated the increase of SOD1 mRNA level in SALS patients tissues compared to controls (Gagliardi et al., 2010). Herein, we described SOD1, TARDBP and FUS mRNA levels and protein aggregation in PBMCs of mutated, non-mutated sporadic ALS patients (SALS) and sex- and age-matched healthy subjects. We analyzed 70 SALS and 70 controls for SOD1, TARDBP, FUS by Real Time PCR. We also included SALS patients mutated in SOD1 (L106F), TARDBP (A382T) and FUS (R521C).
We also performed immunofluorescence experiments to morphologically evaluate the sub-cellular distribution and appearance of the three proteins in lymphoblasts of mutated, non mutated patients and matched controls.
We confirmed that SOD1 mRNA level was up-regulated in ALS patients compared to controls and, interestingly, SOD1 expression in mutated patient was higher than in non-mutated patients.

We demonstrated that the higher level is determined by the mutated allele.
Immunofluorescence of lymphoblasts showed the presence of SOD1 cytoplasmatic inclusions in SOD1 mutated patient and sporadic cases. Small aggregates were also observed in patients mutated in FUS. About TARDBP expression, we showed that the mRNA level was similar between SALS and controls but we evidenced that the TARDBP expression in the mutated SALS patient was higher than controls and SALS non mutated. As SOD1, the higher mRNA level was regulated by the mutated allele. Large round-shaped cytoplasmatic speckles were evident in the patient with mutation in TDP-43, while smaller inclusions were present in sporadic cases.
Finally, we measured FUS mRNA level in SALS patients, in mutated cases and controls and no difference were detectable among these groups. Immunofluorescence experiments showed a diffuse distribution of FUS protein in the nuclear compartment of lymphoblasts from all ALS cases as well as control subjects. We demonstrated that genetic mutations can impact both gene expression and protein aggregation. In fact, mutations in SOD1 and TARDBP gene direct correlate with mRNA level and distribution of the protein aggregation.About FUS, we hypothesized that its involvement in ALS is not related to gene expression and protein aggregation, but, concerning the mutated patients, a distinct clinical phenotype seems to characterize cases carrying the R521C mutation (Corrado et al., 2009). Only samples with different FUS mutations may clarify these data. We will amplify our study by recruitment SALS patients with different mutations in SOD1, TARDBP and FUS genes to confirm our data.

Title: Regulation of the cytoskeleton in spinal muscular atrophy (sma)

Authors: N. HENSEL, B. FÖRTHMANN, H. BRINKMANN, *P. CLAUS;
Neuroanatomy, Hannover Med. School, Neuroanatomy, Hannover, Germany

Abstract: SMA is a neurodegenerative disease caused by progressive degeneration of motoneurons in the spinal cord due to deletion or mutation of the survival of motoneuron (Smn1) gene. In our previous work we have analyzed how SMN regulates neurite growth in neuronal cells. Loss of SMN severely affects regulation of the actin cytoskeleton by dysregulation of the Rho-kinase (ROCK) pathway (van Bergeijk, 2007; Nölle et al., 2011). The SMN-binding protein profilin is the functional link between SMN and this pathway. SMN binds to profilin2 and this interaction becomes interrupted by SMN loss or due to the SMN point mutation S230L close to the profilin2 binding domain. As a consequence, more profilin2 binds to ROCK resulting in its hyper-phosphorylation by ROCK.
Which ROCK downstream molecules are responsible for axonal pathology and possible protection in SMA? In this study, we further dissected the molecular pathway by evaluating the individual roles of downstream targets in disease pathology. Since we have previously found dysregulations of LIMK/cofilin, profilin2a and MLCP at the level of phosphorylation in vitro and in vivo, we wanted to determine which of these targets affect motility-based processes and destabilize axons in SMA. Moreover, we analyzed the effects of activation and inhibition, respectively, of the ROCK pathway as well as ERK signalling, which is functionally linked to ROCK, on neurite outgrowth in an cellular SMA model.
ROCK is a central hub for signal integration and regulation of the actin cytoskeleton as well as actomyosin activitiy. Interestingly, ROCK inhibition by Y27632 or Fasudil improves the lifespan of SMA mice (Bowerman et al., 2010). ROCK inhibition could reverse the observed hyper-phosphorylation of its profilin downstream target. Remarkably, mutations of phosphorylation sites of profilin1 have recently been linked to the pathogenesis of the motoneuron disease amyotrophic lateral sclerosis (Wu et al., 2012). On the basis of these data, we hypothesize that cytoskeletal changes including both actin- and myosin-based processes could be relevant for disease pathogenesis in SMA.

Title: Reduced protein translation rates in a *Drosophila* model for GARS-associated CMT peripheral neuropathy

Authors: *E. STORKEBAUM[1], S. NIEHUES[1], J. BUSSMANN[1], G. STEFFES[1], I. ERDMANN[2,3], S. KOERDT[1], M. LYSAJA[1], D. DIETERICH[2,3];
[1]Mol. Neurogenetics Lab., Max Planck Inst. For Mol. Biomedicine, Muenster, Germany; [2]Res. Group Neuralomics, Leibniz Inst. for Neurobio., Magdeburg, Germany; [3]Inst. for Pharmacoogy and Toxicology, Otto-von-Gluericke-University Magdeburg, Magdeburg, Germany

Abstract: Charcot-Marie-Tooth neuropathy (CMT) is characterized by selective degeneration of peripheral motor and sensory nerves, leading to progressive muscle weakness and wasting and sensory loss. The disease is both clinically and genetically heterogeneous, with currently more than 30 genes causally linked to CMT. Dominant mutations in at least three distinct tRNA synthetase genes cause CMT, namely glycyl-tRNA synthetase (GARS), tyrosyl-tRNA synthetase (YARS) and alanyl-tRNA synthetase (AARS). tRNA synthetases catalyze the aminoacylation of tRNAs with their cognate amino acid, and are therefore essential for protein synthesis.
The fact that dominant mutations in three tRNA synthetases cause CMT suggests that alteration of a common function of these enzymes could be the cause of disease, most probably the canonical aminoacylation activity. However, we and others have previously shown that loss of aminoacylation activity *per se* is not necessary to cause disease, as some CMT-associated mutations do not affect enzymatic activity. However, this does not exclude the possibility that CMT mutations could alter the subcellular localization of the mutant enzymes, what may lead to defects in local protein synthesis.
We here report the generation and characterization of a *Drosophila* model for GARS-associated CMT. A number of hallmarks of the human disease are recapitulated in our *Drosophila* model, including motor performance deficits, reduced life span, defects in neuromuscular junction morphology, and defects in sensory neuron morphology. Furthermore, we studied the subcellular localization of the mutant GARS proteins, but did not find any alterations, indicating that defects in local protein synthesis due to altered subcellular localization is unlikely. We nevertheless evaluated protein synthesis rates in motor neurons *in vivo*, using FUNCAT and BONCAT technology to label newly synthesized proteins. Unexpectedly, we found significantly reduced protein translation rates upon expression of two of the three mutant GARS transgenes. Possible underlying mechanisms will be discussed.
In conclusion, the use of a novel technology has allowed us to detect, for the first time, reduced global protein translation rates induced by a CMT-mutant tRNA synthetase. Our findings may provide important new insights into the molecular pathogenesis of CMT associated with mutations in tRNA synthetases.

Abstract: Charcot-Marie-Tooth (CMT) disease is the most common hereditary peripheral neuropathy for which there is no effective therapy. CMT type 2D is caused by dominant mutations in *GARS* gene, encoding glycine tRNA synthetase (GlyRS). Despite the ubiquitous requirement for this cytoplasmic enzyme in protein synthesis, mutations in GlyRS cause selective peripheral axon degeneration leading to deficits in distal motor function. Previous genetic studies indicate that CMT2D is caused by a neomorphic function of GlyRS mutants (i.e. gain-of-function), but the underlying molecular mechanism is still not known. Our biochemical and cellular data has unmasked a novel non-canonical biological pathway in which mutant GlyRS is secreted and binds competitively with a neurotropic factor to its receptor. Importantly, this mutant-specific interaction interferes with the neurotropic pathway, controlling the progression of the neuropathy in a mouse model of CMT2D. These studies lead to a paradigm shift in our understanding of the function of GlyRS in CMT2D pathogenesis, shedding light on innovative treatment for this disease.

Title: Modeling the early phenotype at the neuromuscular junction of spinal muscular atrophy using patient-derived iPSCs

Authors: *M. YOSHIDA, S. KITAOKA, N. EGAWA, M. YAMANE, K. TSUKITA, T. NAKAHATA, H. INOUE, M. SAITO;
Ctr. For Ips Cell Res. and Application, Kyoto, Japan

Abstract: Objective: To establish an in vitro model of neuromuscular junction (NMJ) connectivity using motor neurons differentiated from spinal muscular atrophy (SMA) patient-derived induced pluripotent stem cells (iPSCs) in order to evaluate the major factors contributing to the pathogenesis of SMA.
Background: SMA is a neuromuscular disorder caused by mutations of the survival of motor neuron 1 (SMN1) gene. It remains unclear why the reduction of the ubiquitously expressed SMN protein selectively affects the neuromuscular system in SMA patients. Recent findings suggest that impaired NMJ formation is an important hallmark in SMA. However, the contribution of NMJ pathology to the pathogenesis of SMA remains unclear due to the limited availability of tissue samples.
Design/Methods: We established human iPSCs from SMA patients and healthy control subjects. The iPSCs were differentiated into motor neurons, and were co-cultured with mouse myotubes to form NMJ *in vitro*. The number of motor neurons and the mean area of acetylcholine receptor (AChR) clustering were evaluated by immunocytochemistry.
Results: While AChR clustering was successfully established on myotubes co-cultured with control iPSC-derived motor neurons, this was significantly impaired in those cultured with SMA iPSC-derived motor neurons. On the other hand, no significant neuronal death was observed in the SMA iPSC-derived motor neurons compared to those from healthy controls.
Conclusions: We successfully developed an *in vitro* model of NMJ,
and by using SMA-iPSCs, we demonstrated that low levels of SMN in the motor neurons are responsible for the impairment of AChR clustering. Our findings imply that the loss of neuromuscular connections appears prior to motor neuronal death, thus suggesting that the NMJ defect is likely to be a major contributing factor to the pathogenesis of SMA. The current *in vitro* NMJ model is useful to dissect the pathophysiological mechanisms underlying the development

of SMA, and to evaluate the efficacy of new therapeutic approaches.

Title: Function of ZPR1 in neurodegeneration and pathogenesis of SMA

Authors: *L. D. GANGWANI[1], N. GENABAI[1], S. AHMAD[2];
[1]Biomed. Sci., Texas Tech. Univ. Hlth. Sci. Ctr., El Paso, TX; [2]Georgia Regents Univ., Augusta, GA

Abstract: Background: Spinal muscular atrophy (SMA) is caused by mutations of the *Survival Motor Neurons* (*SMN1*) gene. SMA is characterized by degeneration of spinal motor neurons caused by low levels of SMN protein. The copy number of the *SMN2* gene primarily influences the severity of SMA. Additional modifier genes that lie outside the SMA locus exist and one gene that could modify SMA is the *Zinc Finger Protein* (*ZPR1*) gene. Currently, there is no treatment available to cure or reduce the burden of severity of SMA because of limited knowledge of modifier genes and the molecular mechanisms associated with SMA pathogenesis.
Objective: To examine the role of ZPR1 in spinal cord motor neuron degeneration and pathogenesis of SMA.
Methods: *In vivo* studies using *Zpr1* knockout and SMA model mice. *In vitro* studies using cultured primary spinal cord neurons.
Results and Discussion: To test the significance of ZPR1 down-regulation in SMA, we examined the effect of reduced ZPR1 expression in mice with mild and severe SMA. We report that the reduced ZPR1 expression causes increase in the loss of motor neurons, hypermyelination in phrenic nerves, increase in respiratory distress and disease severity that reduces lifespan of

SMA mice. The deficiency of SMN-containing sub-nuclear bodies correlates with the severity of SMA. ZPR1 is required for accumulation of SMN in sub-nuclear bodies. We report that ZPR1 overexpression increases levels of SMN and promotes accumulation of SMN in sub-nuclear bodies in SMA patient fibroblasts. ZPR1 stimulates neurite growth and rescues axonal growth defects in SMN-deficient spinal cord neurons from SMA mice. These data suggest that the severity of disease correlates negatively with ZPR1 levels and ZPR1 may be a protective modifier of SMA.
Conclusions: ZPR1 deficiency causes defects in phrenic nerve that may contribute to respiratory distress and increase severity of SMA. Because SMA patients express low levels of ZPR1, our data suggest phrenic nerve as a potential therapeutic target to reduce the burden of respiratory distress in SMA. ZPR1 overexpression elevates SMN levels, corrects the defect in nuclear accumulation of SMN in SMA patient cells and rescues the axonal growth of SMN-deficient neurons from SMA mice. These findings suggest that ZPR1 may be a protective modifier of SMA and opens new avenues for SMA therapeutics.

Title: Mouse muscleblind-like compound knockout models of myotonic dystrophy

Authors: *K.-Y. LEE[1,2,4], M. LI[1,2], M. MANCHANDA[1,2], D. FINN[1,2], A. KUMAR[1,3], T. FOSTER[1,3], M. SWANSON[1,2];

[2]Mol. Genet. and Microbiology and the Ctr. for NeuroGenetics, [3]Neurosci., [1]Univ. of Florida, Gainesville, FL; [4]Neurol., Chang Gung Mem. Hosp., Keelung, Taiwan

Abstract: The muscleblind-like (MBNL) proteins are RNA binding factors that regulate alternative splicing during development by promoting the production of adult protein isoforms. The *MBNL* family consists of three genes, *MBNL1*-3, and we have proposed that sequestration of all three MBNL proteins by the toxic C(CUG) repeat expansion RNAs expressed from mutant *DMPK* and *CNBP* genes causes the multisystemic disease myotonic dystrophy (dystrophia myotonica, DM). To test this hypothesis, we have previously reported the generation of *Mbnl1*, *Mbnl2* and *Mbnl3* knockout (KO) mice. Although Mbnl1 and 2 proteins are expressed in the majority of adult somatic tissues and recognize RNAs via a similar YGCY binding motif, *Mbnl1* KO mice recapitulate several skeletal muscle features of DM while *Mbnl2* KO mice are a good model for DM-relevant CNS disease. To test if loss of both Mbnl1 and Mbnl2 resulted in additional skeletal and cardiac muscle phenotypes associated with DM, we generated *Mbnl1*; *Mbnl2* compound KO mice. While *Mbnl1*$^{-/-}$; *Mbnl2*$^{-/-}$ double KOs are embryonic lethal, *Mbnl1*$^{-/-}$; *Mbnl2*$^{+/-}$ KOs are viable but have a limited lifespan and develop skeletal muscle weakness/wasting as well as heart conduction block, which are cardinal features of DM missing in *Mbnl1* and *Mbnl2* single KOs. These additional DM phenotypes likely result from an increase in defective splicing regulation and the nearly complete reversal to fetal isoform expression in adults that results from depletion of Mbnl2 in the *Mbnl1* KO background. This study supports the MBNL loss-of-function hypothesis for DM and provides additional genetic models for this RNA-mediated disease.

Title: Longitudinal neuromuscular responses in mdx mice challenged with or without addition of forced exercise

Authors: *A. E. KUDWA, Y. JIMENEZ, D. GOMEZ, A. SANCHEZ, R. STEVENSON, B. ALOSIO, R. MUSHLIN, K. CIRILLO, S. RAMBOZ;
Target Validation, Psychogenics Inc., TARRYTOWN, NY

Abstract: Duchenne muscular dystrophy (DMD) is a lethal X-linked neuromuscular disease caused by a mutation in the dystrophin gene, and the *mdx* mouse is the most widely used model of DMD used in preclinical therapeutic screening. Many neuromuscular diseases such as DMD are characterized by an exaggerated exercise-induced fatigue response, disproportionate to activity level, known as fatigability which is observed in both DMD patients and the *mdx* mouse. As such, we developed a hind limb fatigue challenge (HLFC) test utilizing postural fatigue and identified a robust, early *in vivo* fatigability phenotype in the *mdx* mouse. In the HLFC test, subjects are evaluated in a locomotor task, are then forced to stand on their hind limbs for an extended period of time, and are subsequently evaluated in the same locomotor task. Whereas other exercise paradigms such as the running wheel or treadmill can be used to elicit whole body fatigue incorporating more robust cardiopulmonary components, the HLFC test isolates the fatigue to the hindlimb muscles, and we observe consistent early differences in fatigability between *mdx* and control animals. However, as the *mdx* mouse exhibits substantial muscle regeneration leading to a mild progression of the disease, the extent of muscle pathology in sedentary adult mdx mice is low and running wheel or treadmill exercise are often used to exacerbate myofibre necrosis, biomarkers indicative of muscle damage, and behavioral deficits. Therefore, the current study directly compares cohorts of mice evaluated in the HLFC longitudinally with or without exercise in between HLFC testing ages. Ultimately, our goal is to develop a behavioral battery which will reliably capture neuromuscular deficits and provide for efficient and robust preclinical testing in the *mdx* mouse model of DMD. The effectiveness of currently used compounds with therapeutic value in DMD patients, such as prednisone, will be screened using the newly established efficacy study platform.

Title: Inhibitor of hematopoietic prostaglandin D synthase improves the muscle disorder in an experimental model of Duchenne muscular dystrophy

Authors: K. TANAKA[1,2], K. ARITAKE[2], K. MIYOSHI[1], *Y. HAYASHI[1], E. SASAKI[1], Y. URADE[2];

[1]Taiho Pharmaceut. Co., Ltd., Tsukuba, Japan; [2]Dept. of Mol. Behavioral Biol., Osaka Biosci. Inst., Suita, Japan

Abstract: Duchenne muscular dystrophy (DMD) is a fatal genetic disease. The fibers of muscle in DMD patients easily suffer necrotic change, because of the loss of dystrophin that is a membrane protein which links the intracellular cytoskeleton to the extracellular matrix. Thus the patients present with a weakening motor activity. There is still no complete cure for the disease. However, we recently reported that prostaglandin D_2 (PGD_2) synthesized by hematopoietic prostaglandin D synthase (HPGDS) may play an important role in the pathology of DMD, especially muscle necrosis. In this study, to determine the beneficial effect of HPGDS inhibition in therapy for DMD, we evaluated the effect of a highly selective inhibitor, which is a 2-phenoxypyrimidine-5-carboxamide derivative (TFC-007) found in our laboratory, in dystrophine-deficient mice.

We used Dystrophin-deficient *mdx* mice (C57BL/6 back ground) and the wild-type mice (C57BL/6). Mice were orally administrated TFC-007 (30 mg/kg/day) or vehicle for 4 weeks from 4 to 8 weeks of age. At 8 weeks of age, we measured the locomotor activity during night-time, collected the mouse urine of at night-time to determine the urinary concentration of tetranor-PGDM, a metabolite of PGD_2, evaluated the volume of necrotic muscle by measuring Evans blue dye leaked to the skeletal muscle after intravenous injection of the dye, and counted the number of necrotic fibers in cross sections of the tibialis anterior muscle (TA).

The locomotor activity at the night-time was significantly lower in *mdx* mice than that in wild-type mice. The dye-leakage was enhanced in *mdx* mice as compared with the wild-type animals. In histological evaluation, many necrotic fibers were detected in TA of *mdx* mice but hardly in wild-type mice. The urinary tetranor-PGDM concentration was significantly higher in *mdx* mice than that in wild-type mice. TFC-007 administration to *mdx* mice significantly suppressed the urinary tetranor-PGDM concentration, reduced both the dye-leakage and the necrotic muscle fibers, and recovered the locomotor activity.

These results indicate that PGD_2 synthesized by HPGDS is involved in the progression of muscular necrosis in DMD and the inhibition of HPGDS would be an effective therapy for DMD.

Title: The effects of Ursodeoxycholic Acid (UDCA) on the function of isolated mdx gastrocnemius and costal diaphragm preparations

Authors: *C. CARLSON[1], D. LUO[2], H. YU[2], R. POTTER[2];
[2]Physiol., [1]Midwestern Univ. Glendale, Glendale, AZ

Abstract: Previous studies using the mdx model for Duchenne muscular dystrophy indicated that daily *in vivo* administration of the NF-kappaB inhibitor, ursodeoxycholic acid (UDCA), significantly increased the whole body tension (WBT), a noninvasive behavioral measure of the forward pulling tension exerted by the limb musculature. The purpose of the present studies was to assess the effects of this treatment on isolated muscle function. One month old mdx mice were treated with daily intraperitoneal (ip) injections of UDCA (40 mg/kg) or vehicle solution (1.02 % NaCl, pH 8.4) for a period of 1 month. At the end of this treatment period, the mice were anesthetized with isoflurane and the gastrocnemius-plantaris muscle preparation was isolated and used for determinations of active isometric tension using direct stimulation *in situ*. In addition, the mice were euthanized and costal diaphragm strips were used to determine active isometric tension with direct stimulation *in vitro*. Initial results indicate that, at 2 months of age, the mdx gastrocnemius-plantaris preparation does not exhibit alterations in optimal length (l_o) or deficits in specific twitch or tetanic tension compared to age-matched nondystrophic preparations. UDCA treatment did not influence any of these muscle function parameters in the mdx gastrocnemius-plantaris preparation. In contrast, the costal diaphragm of vehicle treated mdx mice exhibited a significant reduction in l_0 ($p<0.001$) and specific twitch ($p<0.01$) compared to nondystrophic preparations. Initial results indicate that UDCA treatment significantly increased l_o ($p<0.05$) and significantly increased the specific tetanic tension at 75 ($p<0.05$) and 100 Hz ($p<0.05$). UDCA - induced increases in specific twitch and specific tetanic tension at 25 and 50 Hz just failed to reach significance ($0.05 < p < 0.08$). These results suggest that mdx mice exhibit a deficit in specific tension in the diaphragm primarily because of decreases in l_o that are presumably secondary to sarcomere disorganization. The partial reversal of this deficit by treatment with UDCA and other NF-kappaB inhibitors may indicate partial restorative effects on sarcomere organization in dystrophic muscle.

Title: Autofluorescence optical imaging of the responses to intracortical stimulation in normal mouse models of myotonic dystrophy

Authors: *G. CHEN[1], S. W. CRAMER[1], L. P. W. RANUM[2], M. S. SWANSON[2], T. J. EBNER[1];
[1]Dept. of Neurosci., Univ. of Minnesota, MINNEAPOLIS, MN; [2]Ctr. for NeuroGenetics and the Dept. of Mol. Genet. & Microbiology, Univ. of Florida, Gainesville, FL

Abstract: Patients with myotonic dystrophy (DM) have cognitive as well as motor function deficits with widespread changes in cerebral cortex white matter. In DM1, CUG, and in DM2 CCUG, expansion transcripts sequester muscleblind-like (MBNL) proteins leading to alternative splicing abnormalities that contribute to disease so restoring MBNL activity is a possible therapeutic strategy. In this study, we use autofluorescence imaging, pharmacological and electrophysio-logical techniques to assess cerebral cortical circuit function in vivo in normal and transgenic mouse models of DM.
In normal anesthetized FVB mice, the cerebral cortex is exposed bilaterally and intracortical microstimulation (ICMS) is delivered with a tungsten microelectrode. ICMS with a single pulse in the motor cortical region evokes a center surround inhibitory response in both hemispheres. The surround decrease in fluorescence is completely blocked by bath application of a GABAA antagonist (SR95531), whereas the central increase in fluorescence is greatly enhanced. Train stimulation (10 Hz, 1s) evokes a strong increase in fluorescence in the stimulated hemisphere centered on the electrode and a "mirror" increase in the contralateral hemisphere that are mediated post-synaptically by AMPA and NMDA glutamatergic receptors. The response in the contralateral cortex is mediated by the corpus callosum as it is blocked by microinjection of the neuro-toxin TTX into the corpus callosum with no significant changes ipsilaterally. Blocking nitric ox-ide synthase (with L-NAME) or cyclooxygenase (with indomethacin), major mediators of in-creased blood flow in response to neural activity, has no effect on the responses. Together, these findings demonstrate the neural and post-synaptic origin of these evoked responses.
In Mbnl2 knockout mice, the response to 10 Hz ICMS train stimulation is prolonged and larger regions are activated in both hemispheres of the cerebral cortex. In mice that overexpress

MBNL1 (MBNL1-OE), the inhibitory surround signal evoked by a single pulse stimulus is markedly reduced with a significant increase in the center compared to wild-type mice. The response in the contralateral hemisphere evoked by 10 Hz stimulation is reduced in MBNL1-OE versus wild-type mice. However, the response to ICMS in the ipsilateral cortex is normal. Therefore, altered MBNL1 expression modifies cerebral cortical excitability, including the responses mediated by the corpus callosum and these changes may contribute to the cognitive disorders in DM patients. Further, our results demonstrate that flavoprotein imaging is a useful tool to assess cere-bral cortical function in mouse models of DM.

Title: Neuropsychological assessment of dystrophin isoform induced progression of cognitive impairment in DMD/BMD patients in North West Indian Population

Authors: *R. TYAGI, S. PRABHAKAR, A. ANAND;
Dept. of Neurology, Post Grad. Inst. of Med. Educ. and Resear, Chandigarh, India

Abstract: Duchenne muscular dystrophy [DMD] and Becker's Muscular Dystrophy [BMD] are among the most common type of muscular dystrophy with X-linked inheritance. In DMD patients respiratory failure and cardiomyopathy are the cause of death in their twenties. Progression of BMD is less severe than DMD with late age of onset. Dystrophin isoforms DP140, DP71, DP40, which are predominantly expressed in brain from distinct internal promotors, are known to be associated with cognitive decline. DP71 plays a role in synaptic transmission and plasticity through clustering glutamate receptor by interacting with multi scaffolding proteins. DP40 isoform interacts with presynaptic proteins which plays role in exocytosis. DP140 expresses predominantly during fetal brain development. One third of boys affected with DMD manifest cognitive impairment with mean Intelligence Quotient below 1.0-1.5 SD caused due to mutation in dystrophin gene. Complete analysis of dystrophin gene for deletion and duplication was carried out for patients with clinical features of Duchenne and Becker's Muscular Dystrophy in north-west Indian population using Multiplex Ligation

dependent Probe Amplification (MLPA). Out of 20 patients analysed through MLPA in Neuroscience Research Lab, deletion was detected in 70 % patients. Out of these patients 78 % patients showed mutation in DP140 specific region. Neuropsychological assessment with analysis of sociodemographic factors for these patients would provide a clear evidence of dystrophin isoform specific cognitive deterioration and progression in follow up studies.

Title: Changes in miRNA expression levels over disease course in a mouse model of ALS

Authors: *A. COURTRIGHT, S. VILLA, K. BURGOS, R. METPALLY, S. NASSAR, B. RAKELA, K. VAN KEUREN-JENSEN;
T-Gen, Phoenix, AZ

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a terrifying, fast moving and fatal disease with no treatment. Early therapeutic intervention could change this predicament by creating the potential to slow down disease pathogenesis, or stop it altogether. Finding effective therapeutics for ALS and other neurodegenerative diseases has been hindered, partly because of the inability to diagnose the disease early before significant neuronal loss has occurred, and partly because we do not fully understand the underlying causes of the disease. miRNA expression levels are responsive to alterations in cellular processes, they reflect mechanistic changes that occur in cells/neurons as they are affected by disease, and therefore we could learn a great deal about the changes in cell function that accompany ALS by studying miRNA expression patterns. miRNAs have been found to play a role in most cellular processes and can have very specific temporal, spatial and cell specific expression. Abnormal expression of miRNAs has been detected in association with the cellular dysfunction in neurological diseases, including Multiple Sclerosis, Alzheimer's disease and Parkinson's disease. These studies have even pinpointed alterations in the expression of miRNAs that target key proteins known to be involved in the pathogenesis of disease. Using human subjects we are unable to determine the earliest time point (before symptom onset and diagnosis) that miRNA deregulation can be detected or which tissues are most sensitive to disease-related changes in miRNA expression. In order to address this lack of

data, we used the SOD1G93A mouse model of ALS to examine changing miRNA profiles over key time points in these animals.

Title: Dysregulation of Rac or Rho induces death of motor neurons and activation of these GTPases is altered in the G93A mutant SOD1 mouse model of ALS

Authors: *T. R. STANKIEWICZ[1,2], R. J. BOUCHARD[2], D. A. LINSEMAN[1,2];
[1]Dept. of Biol. Sci. and Eleanor Roosevelt Inst., Univ. of Denver, Denver, CO; [2]VA Med. Ctr. Denver, Denver, CO

Abstract: Numerous studies have demonstrated a critical function for Rho GTPase family members (i.e., Rac, Rho, Cdc42) in neuronal development and survival. Although a pro-survival function for Rac has been reported in several neuronal cell types including motor neurons, the antagonistic relationship between Rac and Rho/Rho kinase (ROCK) signaling in neuronal survival remains poorly understood. In the current study, we examined the effects of targeted inhibition of Rac GTPase on motor neuron survival. Treatment with NSC23766, a selective inhibitor of the Rac-specific guanine nucleotide exchange factors, Tiam1 and Trio, induces death of embryonic stem cell-derived motor neurons. Following inhibition of Rac, motor neurons displayed activation of caspase-3, dephosphorylation of AKT and ERK5, and nuclear translocation of the BH3-only protein Bad. We also examined the effects of a constitutive activator of Rho, CN03, on motor neuron survival in vitro. In a manner similar to inhibition of Rac, constitutive activation of Rho induced a marked loss of neurites and significant cell death. Interestingly, inclusion of the ROCK inhibitor, Y-26732, partially protected motor neurons from either selective inhibition of Rac or constitutive activation of Rho. These data suggest that the balance between Rac and Rho signaling is critical for motor neuron survival. In accordance with this concept, in the G93A mutant Cu,Zn-superoxide dismutase (SOD1) mouse model of

amyotrophic lateral sclerosis (ALS), active Rac1-GTP immunoreactivity was markedly decreased in choline acetyltransferase (ChAT)-positive motor neurons within the lumbar spinal cord of end-stage mutant mice when compared to age-matched wild type littermates. In addition, although immunoreactivity for total RhoB localized principally to nuclei of ChAT-positive motor neurons from wild type mice, RhoB showed a pronounced redistribution to motor neuronal processes in end-stage mice harboring the G93A SOD1 mutation. Collectively, our data demonstrate that Rac and Rho are critical regulators of motor neuron survival and as a result, disruptions in the balance of their activities may contribute to the etiology of motor neurodegenerative diseases such as ALS. Abstract: Little is currently known about the contents of microvesicles that are released from cell populations of the central nervous system or their potential importance in health and disease. We are particularly interested in the differences in the cargo contained within microvesicles released from affected cells in patients with the neurodegenerative disease, Amyotrophic Lateral Sclerosis (ALS) and healthy control subjects. We created Induced Pluripotent Stem (IPS) cell lines from six patients with ALS and two healthy control subjects. The pluripotent stem cells were differentiated into motor neuron cultures. Four of the ALS patients had sporadic forms of the disease, one patient had a TDP-43 mutation, and one patient had a FUS mutation. We used ultracentrifugation to isolate the microvesicles that were released by the cultures into the media. We then used next generation sequencing to characterize the RNA contents of the microvesicles

(including small RNAs) and tandem mass tags for mass spectrometry quantification and identification of protein contents. We report our findings from these experiments.

Title: Targeting a novel gene in amyotrophic lateral sclerosis

Authors: *B. TERZIC[1], B. RAKELA[1], S. VILLA[1], R. BOWSER[2], T. BEACH[3], A. COURTRIGHT[1], R. METPALLY[1], K. VAN-KEUREN JENSEN[1];
[1]Translational Genomics Res. Inst. (tgen), Phoenix, AZ; [2]Barrow Neurolog. Institute, St. Joseph's Hosp., Phoenix, AZ; [3]Banner Sun Hlth. Res. Inst., Sun City, AZ

Abstract: Amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig’s disease, is a devastating illness that causes the degeneration of both upper and lower motor neurons (MN), leading to eventual muscle atrophy. ALS rapidly progresses into paralysis, with patients typically dying within three to five years from the onset of their symptoms (most commonly due to respiratory complications). Even after many years of research and drug trials, there is still no cure, and current therapies only succeed in increasing life-span by approximately three months. In a genome-wide association study conducted by the Translational Genomics Research Institute (TGen), a single-nucleotide polymorphism (SNP) in a novel gene was found to significantly alter risk for ALS. This novel protein exhibits altered levels of protein and mRNA expression throughout ALS disease progression in human subjects and animal models. We previously showed a significant up-regulation of this novel protein’s expression in muscle during end-stages of ALS disease progression in the SOD1G93A mouse model. Recent data from our lab showed a similar trend in human ALS muscle tissue. Mass spectroscopy analysis of proteins pulled down with this novel protein have identified proteins associated with RNA regulation, including gemin and other components of the SMN complex, as well as hnRNPs. To further validate these

findings, we have verified colocalization of these proteins with one another. We hypothesize that this protein plays an important role in ALS pathogenesis, and we will continue to examine its biological function.

Title: Innervation-sensitive FGF-22 and FGFBP1 are necessary to maintain neuromuscular connections

Authors: *M. J. TENGA[1], H. UMEMORI[2], G. VALDEZ[1,3];
[1]Virginia Tech. Carilion Res. Inst., Roanoke, VA; [2]Mol. & Behavioral Neurosci. Inst., Univ. of Michigan Med. Sch., Ann Arbor, MI; [3]Dept. of Biol. Sci., Virginia Tech., Blacksburg, VA

Abstract: The neuromuscular junction (NMJ) undergoes deleterious structural changes before the erosion of motor skills during normal aging and progression of neurodegenerative diseases. This suggests that molecules that function to maintain and repair the NMJ could protect the motor system from a variety of insults. Here, we provide evidence indicating that the muscle-derived factors, fibroblast growth factor (FGF)-22 and the fibroblast growth factor binding protein 1 (FGFBP1), function to prevent the destruction of adult NMJs. In denervated skeletal muscles, there is a significant reduction in expression of both molecules. FGF-22 and FGFBP1 levels are also reduced in hind limb muscles of the SOD1-G93A mouse model for amyotrophic lateral sclerosis (ALS). In addition, there is a significant reduction in FGF-22 levels in aged, 24 month old, skeletal muscles. These results suggested that FGF-22 and FGFBP1 expressions could be under the control of nerve-derived factors. To test this idea, we treated cultured myotubes with the nerve-derived factor, z-agrin. This molecule is required to form and maintain the postsynaptic apparatus in vivo. It is also sufficient to induce the formation the postsynaptic apparatus in cultured myotubes. Z-agrin treatment of cultured myotubes results in a rapid and long-lasting upregulation of FGF-22 but not FGFBP1. To determine the role of FGF-22 in adult NMJs, we examined NMJs in aging FGF-22 null mice. In mice lacking FGF-22, there is an increased incidence of age-related alterations that include augmented postsynaptic fragmentation, partial denervation of muscle fibers, and extrasynaptic vesicle accumulation. Altogether, our data

suggests that FGF-22 and FGFBP1 may play roles in maintaining NMJs during normal aging, and potentially in diseases that affect the neuromuscular junction. These molecules could, therefore, hold therapeutic potential for preserving and reestablishing function of aged, injured, and diseases-affected NMJs.

Title: Role of sensory neurons in the initiation and progression of Amyotrophic Lateral Sclerosis

Authors: *S. VAUGHAN, M. TENGA, Z. KEMP, G. VALDEZ;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Amyotrophic Lateral Sclerosis (ALS) is recognized as a progressive neurodegenerative disease that primarily targets motor neurons, which form neuromuscular junctions (NMJs) with skeletal muscles. The disease causes deleterious changes at the axon terminals of these neurons, leading to denervation of skeletal muscles, axonal degeneration, and ultimately death. Recent findings, however, indicate that ALS affects other neuronal populations in the spinal cord and brain. In this study, we sought to determine the involvement of sensory neurons in the initiation and progression of ALS using the SOD-G93A mouse model for the disease. To start, we examined changes in proprioceptive sensory neurons nerve endings (1a afferents) at muscle spindles. This strategy allowed us to compare pathological changes in sensory and motor neurons innervating the same muscles. We visualized proprioceptive sensory nerve endings and motor axon terminals in the extensor digitorum longus and gracilis muscles using antibodies against synaptotagmin-2 and neurofilament. In animals showing mild and severe ALS symptoms, the incidence of degenerating axons is similar between proprioceptive sensory neurons and motor neurons, irrespective of the muscle examined. We then visualized sensory synapses in the ventral horn of the spinal cord, primarily those formed with motor neurons. As in muscle spindles, there is a significant decrease in the number of vesicular glutamate transporter 1 (VGLUT1) positive synapses in the ventral horn of ALS-afflicted spinal cords. Interestingly, we found an increase in the number of parvalbumin-positive synapses, suggesting that proprioceptive axons sprout in the spinal cord potentially to compensate for loss of other synaptic inputs on motor neurons. These synaptic changes, along with changes in the

soma of sensory neurons, strongly suggest a key role for sensory neurons in ALS. It also demonstrates that the location of proprioceptive axons determines their response to ALS. These findings indicate that an effective therapeutic for ALS must also be designed to protect sensory neurons.

Title: Oligodendroglia significantly contribute to neuronal injury in ALS

Authors: *Y. LI[1], D. BERGLES[2], J. D. ROTHSTEIN[3];
[1]The Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [2]Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [3]Brain Sci. Institute, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Amyotrophic lateral sclerosis (ALS) is a fatal disease characterized by the loss of upper and lower motor neurons along with interneurons with unknown etiology. Recently we have amassed data suggesting that oligodendroglia contribute to ALS pathogenesis. Proliferating and reactive oligodendrocyte progenitor (OPCs, also known as NG2+ glia) are present in the lumbar spinal cord ventral horn gray matter where motor neurons die in a SOD1 ALS mouse model. We recently reported that oligodendroglia degenerate during disease development leading to loss of gray matter myelin. Changes in oligodendroglia, NG2 cells and myelin were also seen in human ALS motor cortex and spinal cord. Furthermore, oligodendroglial specific monocarboxylate transporter 1 (MCT1) expression is decreased in ALS mice and human ALS CNS. Given that oligodendrocytes not only facilitate saltatory conduction of action potentials by myelinating axons, but also support neuronal functions metabolically through MCT1, the injury to oligodendroglia in ALS may have pathogenic consequences. Therefore, to further investigate the role of oligodendrocytes in ALS pathogenesis, we selectively removed mutant hSOD1

(G37R) from oligodendrocyte progenitors in *PDGFαR-CreER;loxSOD1(G37R)* mice. The 4-hydorxytamoxifen (4HT) treatment caused significant decrease in the mutant human SOD1 transgene expression in OPCs. We found that excision of mutant hSOD1 from OPCs dramatically delayed disease onset and early disease, and significantly prolonged animal survival. In addition, at disease onset stage, activated astroglial and microglial responses were delayed in the animals received 4HT treatment. Moreover, the removal of mutant hSOD1 helped to preserve MCT1 expression at disease onset stage. These data indicate that expression of mutant hSOD1 in OPCs and their oligodendrocyte progeny has a deleterious effect on motor neuron survival, and suggest that a key negative consequence of mutant SOD1 expression in oligodendrocytes is to diminish their capacity to provide metabolic support to neurons. To further investigate the mechanisms involved in oligodendrocyte degeneration in human ALS, we differentiated human ALS patient specific induced pluripotent stem cells (mutant SOD1 and C9orf72) to oligodendrocyte progenitors and myelinating oligodendrocytes, and compared their gene expression profiles with those from healthy control subjects. We also examined the effects of the mutant ALS gene(s) on axonal myelination in vitro, as well as survival of motor neurons. The role of human oligodendrocytes in ALS pathogenesis will be further discussed.

Title: Specific motor-unit changes in perisynaptic schwann cell at nmjs of symptomatic $SOD1^{g37r}$ mice

Authors: *D. ARBOUR[1], E. TREMBLAY[2], E. MARTINEAU[2], R. ROBITAILLE[2];
[1]Univ. De Montréal, Montréal, QC, Canada; [2]Physiol., Univ. de Montréal, Montreal, QC, Canada

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by progressive loss of motoneurons and consequent skeletal muscle denervation and neuromuscular junction (NMJ) destruction. A large body of evidence indicates that denervation proceeds in a muscle-specific manner whereby fast functional motor units are preferentially lost compared to slow-twitch muscles. Recent studies have highlighted the implication of glial cells in the disease progression such as activation of axonal Schwann cells at the onset of hind limb paralysis.

However, changes in non-axonal Schwann cells at the NMJ remain ill defined. Perisynaptic Schwann cell (PSCs), glial cells at the NMJ, influence structural stability, integrity and repair of the NMJ and actively decode synaptic activity. Hence, we postulate that PSCs ability to regulate NMJ functions are altered in ALS. NMJs from soleus nerve-muscle preparations of symptomatic (P350 to 380) $SOD1^{G37R}$ mice and their wild type litter mates were used. First, labelling of the three synaptic elements (pre- postsynaptic and PSCs) at symptomatic stage revealed that 25% were denervated, 25% showed signs of poly-innervation and nerve terminal sprouting was often associated with poly-innervation. Second, to test the ability of PSCs to detect synaptic activity, we monitored PSCs calcium responses to endogenous neurotransmitter release. PSCs calcium responses from $SOD1^{G37R}$ mice elicited by nerve stimulation were not different from their littermate, although synaptic efficacy was higher in $SOD1^{G37R}$ mice as revealed by a higher quantal content calculated from intracellular recordings. Ca^{2+} responses induced by ATP were smaller in SOD1 type I fiber type but was larger in type IIa muscle fibers. Furthermore, local application of the mAChR agonist muscarine induced higher calcium responses in PSCs of $SOD1^{G37R}$ mice compared to wild type. More specifically, the amplitude of PSCs calcium responses was larger when associated with fast twitch fiber type IIa than with slow muscle fiber type I in $SOD1^{G37R}$ mice. Since PSCs muscarinic receptors are known to regulate NMJ stability and that fast-twitch motoneurons will degenerate first, it seems that PSCs undergo specific motor unit changes to adapt to the disease progression. Overall, our data suggest that the phenotype of PSCs would not be compatible for NMJ plasticity and repair.

Abstract: Mutations in the dysferlin gene lead to LGMD2B and Miyoshi myopathy among other phenotypes. We describe a cohort of 31 patients, from 25 non-related Chilean families, harbouring point mutations in the DYSF gene. Diagnosis was based on clinical findings or absence of dysferlin in muscle biopsies. Assessment workup consisted of clinical evaluation, Motor Function Measure (MFM) scale, CK level, electrodiagnostic testing, whole body MRI, echocardiogram, spirometry and DYSF gene direct sequencing. Eight mutations were consistently found in the cohort, four of which (c.5979dupA; c.2858dupT; c.2779delG and c.4390G>T) accounted for 82% of the mutations found. In four patients only one mutation was found after complete DYSF gene sequencing. The age at symptom onset ranged from 10 to 33 years (mean 20.8), symptoms manifesting invariably as weakness in the legs, distally (21/31) or proximally (10/31), progressing later to the upper limbs. Mean serum CK level was increased 57(±35) times above normal values. Electrodiagnostic assessment showed normal NCV and repetitive stimulation testing, with distinct degrees and distribution of myopathic changes on needle EMG. Single fibre EMG was normal in six confirmed dysferlinopathy patients. Muscle MRI done in 28/31 patients showed impairment with a similar distribution in all patients despite clinical phenotype. Spirometry showed a mild restrictive defect in 3/18 patients at late stages of disease. Echocardiogram performed in 23/31 patients was within normal range. The clinical spectrum of dysferlinopathy in the series is in agreement with similar cohorts reported. The relative high frequency of some mutations suggests a founder effect for such mutations in the Chilean population. We therefore propose to evaluate the effect these recurrent mutations in vesicle trafficking and cell membrane fusion events, using in vitro cell models such as the RCMH human muscle cell line, muscle primary cultures and myogenic cell lines from patients. We will pay special consideration to prevalent Chilean mutations. Regarding the association of dysferlin with the dihydropyridine receptor and proteins such as annexins and AHNAK that are involved in actin organization, we will also evaluate the role of dysferlin in calcium signals and cortical actin organization.

Title: Immunization of mice with muscle specific tyrosine kinase leads to motor nerve alterations

Authors: *V. PATEL[1,2], A. OH[1,2], L. G. SULTATOS[1,2], B. A. WILSON[3], M. HO[3], J. J. MCARDLE[1,2];
[1]Pharmacol. and Physiol., UMDNJ, NEWARK, NJ; [2]Pharmacol. and Physiol., Rutgers New Jersey Med. Sch., Newark, NJ; [3]Microbiology, UIUC, Urbana-Champaign, IL

Abstract: Autoantibodies to muscle specific tyrosine kinase (MuSK) and the acetylcholine receptor (AChR) produce distinct forms of myasthenia gravis (MG). In particular, MuSK-MG patients do not exhibit significant loss of AChRs. Furthermore, transmitter release increases and decreases for AChR-MG and MuSK-MG, respectively. These findings suggest motor nerve dysfunction during MuSK-MG. To test this hypothesis, we utilized a model of MuSK-MG produced in mice immunized with rat MuSK ectodomain. C57B6 female mice were injected with 40 μg of MuSK emulsified in 100 μl of equal volumes of PBS and complete Freund's adjuvant once a month for 3 months; controls were injected with vehicle alone. All MuSK injected mice produced antibodies. However, in vivo evaluation revealed variability in the degree of muscle dysfunction. Therefore, to identify severely affected mice we isolated diaphragm-muscle phrenic-nerve preparations and evaluated mechanical responses to nerve stimulation. For 40% of MuSK injected mice twitch tension was significantly reduced from the control value of 4.75 ± 0.19 (n=10) to 2.87 ± 0.20 grams (n=8). In order to study the neuromuscular junction (NMJ) of these mice, Triangularis sterni nerve-muscle preparations were also isolated. Alterations of motor nerve function were noted for 3 groups of NMJs: Group 1 had prolonged endplate currents (EPCs) of reduced quantal content; Group 2 had intermittent failure of EPCs at 20-70 Hz stimulation frequencies; Group 3 had spontaneous but not evoked transmitter release. EPC failures in Group 2 were associated with the absence of nerve terminal currents. Immunohistochemical imaging showed neurofilament-positive swelling as well as abnormal preterminal branching. Both of these alterations would contribute to intermittent as well as complete failure of stimulus-evoked transmitter release. These findings support the hypothesis

that MuSK-MG is associated with motor nerve dysfunction while providing novel insight into the pathophysiology of the disease.

Title: Investigation of semaphorin3a as a regulator of motor axon reinnervation at the neuromuscular junction

Authors: *J. SHADRACH, B. PIERCHALA;
Biologic and Material Sci., Univ. of Michigan, Ann Arbor, MI

Abstract: Motor function is achieved by proper communication between motor neurons and muscle fibers at a specialized synapse called the neuromuscular junction (NMJ). Throughout life the maintenance of the NMJ is an active process that requires the coordinated effort of three main cell types: the presynaptic motor neuron (MN) terminal, the postsynaptic muscle fiber, and terminal Schwann cells (TSCs). Both traumatic injury and neurodegenerative diseases, such as amyotrophic lateral sclerosis (ALS), can result in acute or chronic NMJ denervation, respectively. Under those conditions denervation triggers a regenerative response in which motor nerve terminals are stimulated to grow and undergo axonal sprouting as they reinnervate muscle fibers. Many studies suggest that reestablishment of neuromuscular connections is mediated by various axonal guidance molecules, of which Semaphorin3A (Sema3A) may be of particular importance. Sema3A is a secreted glycoprotein that binds to a plexin-neuropilin-1 receptor complex and initiates downstream signaling cascades that induce growth cone collapse and axonal repulsion. Although recently it was discovered that TSCs and isolated muscle cells can upregulate Sema3A mRNA in response to nerve and muscle injury, preliminary data we have generated suggests that Sema3A protein is localized to the area surrounding the NMJs under normal, resting conditions and is dramatically decreased in response to both acute, chemically-induced muscle injury and during the later stages of neurodegeneration in the ALS G93A-SOD1 transgenic mouse model. Ongoing work utilizing a newly generated Sema3A-GFP reporter line and other transgenic models are aimed at identifying which cell types within the skeletal muscle

produce Sema3A, what conditions are required for that to occur, and how production of Sema3A functionally impacts reinnervation and/or maintenance of the NMJ.

Title: Responses to VPLo thalamus stimulation in primary motor cortex

Authors: *F. AGNESI[1], A. T. CONNOLLY[1], J. XIAO[1], M. D. JOHNSON[1,2];
[1]Univ. of Minnesota, Minneapolis, MN; [2]Inst. for Translational Neuroscience, university of Minnesota, Minneapolis, MN

Abstract: The cerebellar-receiving area of motor thalamus has been the primary anatomical target for deep brain stimulation therapy in cases of Essential Tremor. Despite the clinical successes of the therapy, little is known about how motor thalamus stimulation modulates intracortical dynamics within primary motor cortex (M1). In this study, we investigated spontaneous spike activity in M1 during low-frequency (10-30 Hz) and high-frequency (100 Hz) electrical stimulation in the VPLo (ventralis lateralis posterior pars oralis nucleus of thalamus) in a non-human primate. VPLo stimulation was delivered using a tungsten microelectrode inserted into regions responsive to arm movement and susceptible to stimulation-evoked arm movements at low stimulation amplitudes (<30 μA). Behaviorally, low frequency (10-30 Hz) VPLo micro-stimulation never elicited movement, even at higher intensities (60 μA). Higher frequencies (100 Hz) occasionally elicited brief movements at stimulation onset but never induced sustained muscle contractions. Microelectrodes were also inserted into the arm region of M1 (also identified by low threshold stimulation for evoking arm movements), and the activity of single neurons was recorded before, during and after delivery of VPLo micro-stimulation. Peri-stimulus time histograms triggered to each stimulation pulse were constructed and the cumulative sum technique was used to evaluate significance of alteration in firing patterns. We recorded a total of 52 cells and observed two prototypical responses. The first consisted of a sharp increase in the probability of spike activity 3 ms following a stimulus pulse, indicative of stimulating mono-synaptic glutamatergic projections to M1 (10/52 cells). This pattern was most evident for VPLo stimulation at higher frequencies. The second response type consisted of a broad excitation peak

centered at a delay of ~30 ms from the start of the interstimulus interval (10/52 cells), but only at the 10 Hz stimulation frequency. Both responses were observed in the same cell only once. Our data suggests the presence of two pathways excited by VPLo HFS: one direct, inducing short-delayed monosynaptic excitation with low jitter, and one indirect involving multiple synapses.

Title: Cis-regulatory elements of POLG1 expression with putative tissue-specificity

Authors: *J. P. NIKKANEN, J. PARTANEN, A. WARTIOVAARA;
Univ. of Helsinki, Helsinki, Finland

Abstract: Polymerase gamma is the only known mitochondrial DNA (mtDNA) replicative polymerase. It consists of a catalytic subunit (POLG1) and two accessory subunits (POLG2). POLG1 mutations are one of the most common causes of mitochondrial disorders and of inherited causes of neurodegeneration, in general. Over hundred disease mutations are found within its coding region. In spite of apparently constitutive expression, the manifestations are highly tissue-specific. One of most common symptom is progressive sensory neuropathy. The basis of the highly specific manifestations is unknown. We have studied POLG1 expression regulation and identified three conserved nervous system specific enhancer modules that are likely to regulate POLG1 tissue-specific expression. We further characterized these enhancers by constructing mouse lines showing the tissue-specific expression pattern throughout development and in adult mice. Two of the enhancers are functional in adult brain and spinal cord, whereas one was found to be specific for the development of the central nervous system. Interestingly, these enhancers locate in the introns of a long intergenic non-coding RNA (lincRNA). We studied the lincRNA and POLG1 transcript levels in different regions of the central nervous system and noticed that they strongly correlate. This was further validated by lincRNA knock-down experiment and therefore we suggest that this lincRNA is regulating POLG1 expression in the central nervous system, possibly together with the characterized enhancer modules. Based on our studies in the spinal cord, we suggest that the subpopulation of neurons of the dorsal horn and dorsal root ganglia, where the enhancers drive expression, might be involved in the

development of sensory neuropathy in POLG1 patients. This is the first study showing tissue-specific expression regulation of an essential mtDNA maintenance protein.

Title: Transient up-regulation of Pax6 increases glutamatergic neuronal differentiation in prefrontal cortex of an animal model of autism

Authors: *K. KIM[1,2], C. CHOI[3], J.-W. KIM[3], M.-R. SONG[5], J. CHEONG[6], C. SHIN[4]; [1]Col. of pharmacy, Col. of Pharmacy, Seoul Natl. Abstract: Imbalance in excitatory/inhibitory signal in the brain has been suggested as a one of the main pathological features in autism spectrum disorders (ASDs), although the underlying cellular and molecular mechanism is unclear yet. Because excitatory/inhibitory imbalance can be induced by aberration in glutamatergic/GABAergic neuronal subtype differentiation, we investigated the mechanism of dysregulated neuronal differentiation between excitatory and inhibitory neurons in the embryonic and postnatal brain of prenatally valproate-exposed rat offspring, which is often used as an animal model of ASDs. Transcription factor Pax6, implicated in glutamatergic neuronal differentiation, was transiently increased in embryonic cortex by VPA exposure, which resulted in the increased expression of glutamatergic proteins in postnatal brain of offspring. Chromatin immunoprecipitation showed increased acetylated histone binding on *Pax6* promoter region, which may underlie the transcriptional up-regulation of Pax6. Other HDAC inhibitors (HDACi) including TSA and SB but not valpromide, which is devoid of HDACi activity, induced Pax6 up-regulation. Silencing Pax6 expression in cultured rat primary neural progenitor cells demonstrated that up-regulation of Pax6 plays an essential role in VPA-induced glutamatergic differentiation. Blocking glutamatergic transmission with MK-801 or Memantine treatment, and to a lesser extent with MPEP treatment, reversed the impaired

social behaviors and seizure susceptibility of prenatally VPA-exposed offspring. Together, environmental factors may contribute to the imbalance in excitatory/inhibitory neuronal activity in autistic brain by altering expression of transcription factors governing glutamatergic/GABAergic differentiation during fetal neural development, in conjunction with the genetic preload.

Title: Reduced axonal localization of a Caps2 splice variant impairs axonal release of BDNF and causes autistic-like behavior in mice

Authors: *T. SADAKATA;
Advanced Scientific Res. Leaders Develop. Unit, Gunma Univ., Maebashi, Japan

Abstract: Ca2+-dependent activator protein for secretion 2 (CAPS2 or CADPS2) potently promotes the release of brain-derived neurotrophic factor (BDNF). A rare splicing form of CAPS2 with deletion of exon3 (dex3) was identified to be overrepresented in some patients with autism. Here, we generated Caps2-dex3 mice and verified a severe impairment in axonal Caps2-dex3 localization, contributing to a reduction in BDNF release from axons. In addition, circuit connectivity, measured by spine and interneuron density, was diminished globally. The collective effect of reduced axonal BDNF release during development was a striking and selective repertoire of deficits in social- and anxiety-related behaviors. Together, these findings represent the first mouse model of a molecular mechanism linking BDNF-mediated coordination of brain development to autism-related behaviors and patient genotype.

Title: Altered neuroplasticity of the amygdala in valproate-induced rat autism model

Authors: *H.-C. LIN[1,2], Y.-H. CHAN[3], P.-S. CHEN[4];
[1]Dept. and Inst. of Physiology, Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Brain Res. Ctr., Natl. Yang-Ming Univ., Taipei, Taiwan; [3]Dept. of Pharmacology, Col. of Medicine, Natl. Cheng Kung Univ., Tainan, Taiwan; [4]Dept. of Psychiatry, Addiction Res. Center, Hosp. and Col. of Medicine, Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: Clinically, exposure of epileptic patients to valproic acid (VPA), an epigenetic regulator, during the period of pregnancy could cause developmental delays and increase the risk of autism in the child. Among the rodent models of autism, prenatal or postnatal exposure to VPA during the critical period had also been demonstrated to lead to autistic phenotypes. Amygdala is the brain area involved in socio-emotional behavior. However, the role of amygdala in autism remains inconclusive. Here, we used 28-35 days valproate (VPA)-induced rat model of autism to observe the autistic phenotypes and evaluate their synaptic characteristics in the lateral nucleus (LA) of the amygdala. The VPA-exposed offspring demonstrated less social interaction and increased anxiety. Slice preparation and electrophysiological recordings of the LA were performed in the VPA- exposed offspring. The magnitude of long term potentiation (LTP) was significantly higher in the VPA-exposed than saline-exposed offsprings. Whole-cell recordings of the LA pyramidal neurons showed an increased miniature excitatory postsynaptic current (EPSC) frequency and amplitude. These results indicated the enhancement of synaptic plasticity and excitatory synaptic transmission in the LA might contribute to autism in the VPA exposed offspring.

Title: Mechanotransduction of hippocampal neurons: Role of ubiquitin ligase E3a (Ube3a) in neurite contact guidance

Authors: *I. TONAZZINI[1], G. M. VAN WOERDEN[2], S. MEUCCI[1], Y. ELGERSMA[2], F. BELTRAM[1], M. CECCHINI[1];
[1]NEST, Scuola Normale Superiore and Inst. Nanoscience CNR, Pisa, Italy; [2]Dept. of Neurosci., Erasmus Med. Ctr., Rotterdam, Netherlands

Abstract: In the brain, all cells are exposed to extracellular stimuli determined by the micro/nano-environment within which they exist, with the local extracellular domain of each cell orchestrating the wiring of the CNS. In fact, neurite initiation is critically controlled by the establishment/maturation of Focal Adhesions (FAs- protein clusters anchoring integrins to cytoskeleton) that in turn coordinate cell polarity and neurite pathfinding/ motility. Recently groups started investigating the processes that regulate neuronal adhesion and migration, using nano-textured substrates, shown to be capable of tuning neuronal differentiation, polarity and neurite orientation.
Here, we studied the mechanotransduction of hippocampal neurons and the role of ubiquitin ligase E3a (Ube3a), whose loss of function causes the neurodevelopmental disorder Angelman Syndrome (OMIN 105830), in neurite contact guidance during path finding. Recent data suggest that the loss of Ube3a expression is associated with defects in neuronal connectivity and morphology, in several brain areas. To test this further we exploited biocompatible nanogratings (NGs, substrates with patterns of sub-um lines of grooves and ridges) with different topographical characteristics (line-widths ranging from 0.5um to 1um) fabricated by nanoimprint lithography on a cyclic olefin copolymer thermoplastic polymer film. NGs were coupled with Wild-Type (WT) and Ube3a-KO primary mouse hippocampal neurons and neuronal topographical sensing was studied as neurite contact guidance with the aim to compare the capability of WT and Ube3a-KO neurons to read and follow physical directional stimuli. As expected, WT neurons could polarize along the NGs, showing very efficient neurite alignment. Interestingly, in Ube3a-KO neurons mechanotransduction is less efficient, as highlighted by an overall loss of cell polarization and neurite alignment. In order to evaluate if this behavior is due to altered adhesion mechanisms in Ube3a-KO neurons, the activation and maturation of FA complexes were investigated. Because interactions have been found between Focal Adhesion Kinase (FAK) and Paxillin (PAX) and αCaMKII, the protein dysregulated in Ube3a-KO mice**,** we focused our analysis on these proteins.
In summary, we report impaired mechanotransduction in Ube3a-KO neurons, resulting in less efficient neurite contact guidance. Our results are in agreement with the hypothesis that the loss of Ube3a would result in abnormal neuronal connectivity/shaping, leading to pathological

neuronal plasticity. This work was supported by the EU FP7 program, grant no. NMP4-LA-2009-229289 NanoII.

Title: Gastrointestinal dysfunction mediated by GABAA receptors in the Neuroligin-3R451C mouse model of autism

Authors: *E. HILL-YARDIN[1], M. ELLIS[1], N. OEZGUEN[2], T. SAVIDGE[2], J. C. BORNSTEIN[1];
[1]Univ. of Melbourne, Parkville, Australia; [2]Baylor Col. of Med., Houston, TX

Abstract: Gastrointestinal (GI) disorders are common in patients with autism spectrum disorder (ASD) and reduce quality of life. However, despite association of many genes influencing CNS synaptic function, the etiologies of these GI symptoms are unknown. Mutations in the neuroligin family of synaptic adhesion molecules are implicated in ASD disease progression. In order to identify underlying biological mechanisms, information on the expression of ASD candidate genes and the functional impact of the NL3R451C mutation in the enteric nervous system (ENS) is required.
Methods: Human ASD-associated neuroligin mutations were structurally mapped using homology models generated for human NLG1, 2, 3 and 4Y and aligned to core structured regions of the NLGN4-X crystal structure. Protein-protein interfaces were predicted using the InterProSurf web server. Expression of neuroligins and neurexins was assessed in gut and brain cDNA using RT-PCR. Colonic migrating motor complexes (CMMCs) were analysed in isolated colon segments using video imaging techniques and spatiotemporal maps. CMMCs were assessed at baseline and in the presence of GABAA (bicuculline 10 µM and gabazine 10 µM) and GABAB (CGP 54626; 100 nM) receptor antagonists.
Results: The structural domain harbouring R451C contained 5 of 7 identified mutation sites (Arg451 on NLGN3 and Asp429, Asp396, Val403 and Lys378 on Neuroligin 4X), closely juxtaposed to two protein-protein interface patches. We show expression of Nlgn3, related genes

(Nlgn1 and Nlgn2) and neurexin binding partners (Nrxn 1 and Nrxn 2) in the mouse ENS. Further, both bicuculline (n = 16 WT, n = 16 NL3 R451C) and gabazine (n = 11 WT, n = 11 NL3 R451C) reversibly depressed CMMCs in NL3 mice compared to WT while CGP 54626 (n = 8 WT, n = 9 NL3) had no effect. Bicuculline reduced CMMCs in NL3R451C compared to WT colon (median difference: 6 contractions, 95% CI: 1, 12; p = 0.03). Gabazine also reduced CMMC frequency in NL3R451C mice compared to WT (median difference: 5 CMMCs, 95% CI: 2, 9; p = 0.009). In control conditions, CMMC frequency was identical in WT (n = 70) and NL3R451C (n = 69) tissues; in both WT and NL3 R451C the median number of CMMCs was 4 (WT: 95% CI: 1, 11; NL3 R451C: 95% CI: 1, 15; median difference 1, 95% CI -2, 4; p = 0.509). Conclusion: Positional association of R451C with other clinically identified mutations suggest that a functionally conserved domain in the neuroligin family may be targeted in ASD. We show that the R451C knock-in mutation in the NL3R451C mouse model of ASD causes colonic motility dysfunction via a GABAA receptor mediated mechanism. These data implicate altered enteric synaptic function as a primary underlying cause of GI disorders in ASD.

Title: The Role of MAPK/ERK signaling in ASD pathogenesis associated with copy number variation in 16p11.2 deletion mice

Authors: *J. PUCILOWSKA[1], J. VITHAYATHIL[2], G. E. LANDRETH[3];
[1]Neurosci., [3]Neurosciences, [2]Case Western Reserve Univ., Cleveland, OH

Abstract: Copy number variations (CNVs) of human chromosome 16p11.2 are linked to autism spectrum disorders (ASD), where deletions or duplications of this region account for 1% of all ASDs. The extracellular signal-regulated kinases, ERK1 and ERK2, are the central elements of one of the most prominent signaling pathway governing neural development and synaptic plasticity and are genetically linked to ASDs and cognition. The 16p11.2 human locus contains 27 genes, including the ERK1 gene (MAPK3) and Major Vault Protein (MVP) gene. MVP regulates signaling through the ERKs. A mouse model of the human 16p11.2 microdeletion (the

chr7qF3-deficient mouse) recapitulates some of the behavioral pathology associated with ASD patients. However, the pathophysiological and biochemical mechanisms underlying these abnormalities are unexplored. We propose that altered expression of one or more genes in the 16p11.2 region converges onto the ERK/MAP kinase signaling pathway resulting in deficits associated with ASD.
We developed constitutive ERK1 knockout (ERK1 KO) and conditional ERK2 knockout (CKO) mouse models. These models exhibit deficits which partially phenocopy the behavioral deficits observed in ASD patients. We previously established a mechanism by which ERKs regulate corticogenesis, where loss of ERK activity leads to defects in progenitor proliferation resulting in altered cortical cytoarchitecture, abnormal physiology and behavior. Given the convergence of genetic evidence onto the ERK pathway and their role in neurogenesis we examined the 16p11.2del ASD mice for abnormalities we previously linked to neurodevelopmental disorders of the MAP kinase pathway, including Autism.
We report that: ERKs are hyperactivated in 16p11.2del ASD mice, resulting in aberrant neurogenesis and deficits in postnatal brain cytoarchitecture. Specifically, we observe a 30% decrease in upper cortical projection neurons (Brn1+, SatB2+ neurons) and a 10% increase in layer VI cortico-thalamic, Tbr1+ neurons. Additionally, during mid-neurogenesis, we detect a significant increase in progenitor proliferation in the ventricular and subventricular zone as evidenced by elevated PH3 staining. However, the total number of Tbr2+ intermediate progenitors as well as their generation from Pax6+ radial glia is significantly decreased. We examined the ASD mice for changes in the cell cycle regulator p27KIP1, which is directly targeted by the ERKs and mediates cell cycle progression. We observed a significant decrease in p27Kip1 by Western analysis as well as immunohistochemistry. Furthermore, we report that the 16p11.2del ASD mice are hyperactive and exhibit anxiety-like behaviors.

Title: Reduced GABAergic interneurons density and functional alterations in the visual cortex of Engrailed-2 knockout mice, a murine model for autism

Authors: *M. ALLEGRA[1,2], S. GENOVESI[3], P. SGADÒ[3], M. CENNI[1], Y. BOZZI[3], M. CALEO[1];

[1]Inst. Di Neuroscienze CNR, Pisa, Italy; [2]Scuola Normale Superiore, Pisa, Italy; [3]Lab. of Mol. Neuropathology, Ctr. for Integrative Biol. (CIBIO), Trento, Italy

Abstract: The maturation of the GABAergic system is a crucial determinant of cortical development during early postnatal life, when sensory circuits undergo a process of activity-dependent refinement. An altered excitatory/inhibitory balance has been proposed as a possible pathogenic mechanism of various neurodevelopmental disorders, such as Autism Spectrum Disorders (ASD) and epilepsy.
The homeobox-containing transcription factor Engrailed-2 (En2) has been implicated in the pathogenesis of ASD. Mice lacking En2 (En2-/- mice) display anatomical and behavioural "autistic-like" features, as well as increased seizure susceptibility, a clinical feature frequently observed in ASD patients.
Here we have explored the relationship between GABAergic innervation and maturation of cortical function in En2-/- mice. To address this issue, we have exploited the good knowledge of the anatomical and functional features of the mouse visual system.
First, we analyzed the profile of GABAergic interneurons in the visual cortex. En2-/- mice, when compared to age-matched wild-type (WT) controls, showed a reduction in the number of parvalbumin (PV), somatostatin (SST) and neuropeptide Y (NPY) positive neurons. Quantitative real time RT-PCR experiments confirmed the decreased expression of PV, SST and NPY in En2-/- mice. We next investigated whether the reduced number of GABAergic interneurons results in an altered maturation of visual system in En2-/- mice. At the anatomical level, En2-/- mice displayed a normal eye-specific segregation the retino-geniculate pathway. Visual Evoked Potentials (VEPs) and single units recordings were performed to assess the functional properties of primary visual cortex (visual acuity, contrast threshold and binocularity) in adult WT and En2-/- mice. While basic physiological parameters (acuity, contrast, response latency) developed normally, we found a significantly increased binocularity in En2-/- mice, pointing to a physiologically more immature state of the visual cortex.
These data suggest that a deficient GABAergic inhibition in the visual cortex of En2-/- mice is involved in the altered maturation of cortical binocularity. This study strengthens the notion that GABAergic system dysfunction contributes to cortical circuit alterations in murine models of ASD.

Title: Increased cell proliferation and reduced neural differentiation in the developing hippocampus following postnatal exposure to sodium valproate

Authors: C.-W. CHENG[1], W.-H. WANG[1], C.-S. YANG[3], *S.-F. TZENG[2];
[1]Life Sci., [2]Natl. Cheng Kung Univ., Tainan City, Taiwan; [3]Ctr. for Nanomedicine Res., Natl. Hlth. Res. Institutes,, Zhunan, Taiwan

Abstract: Autism is a neurodevelopmental disorder with impairments in social interaction, repetitive behaviors and interests, as well as cognitive delays. However, the molecular mechanism remains largely unknown. A neurobehavioral model of autism in rodents receiving prenatal or postnatal exposure of sodium valproate (VPA) has been characterized. In our laboratory, we used the model of male rat pups receiving 200 mg/kg of VPA via a bolus of intraperitoneal injection at postnatal day 7. The results from elevated the plus-maze test at 2, 4 and 6 weeks post injection showed the VPA-injected rats exhibited impaired social interaction and anxiety. Through the open field test, we found that VPA-treated rats displayed an anxious behavior and abnormal locomotion. Given the fact that cortex and hippocampus are associated with autistic behaviors, we examined cellular and molecular alterations in the hippocampus of rats at 24 h, 2 w, 4 w, and 6 w. An increased level of acetylated histone H3 was detected at 24 h in cortex and hippocampus of rat pups receiving VPA injection when compared to that observed in vehicle-treated rats. $BrdU^+$-cells or $Ki67^+$-cells in the hippocampus of rats were also increased at the four observed time points after VPA exposure. In addition, neuronal differentiation gene, NeuroD, was decreased in the hippocampus of VPA-treated rats at the four detected time points. Olig1 and olig2 gene expression was also downregulated, but GFAP mRNA expression was increased in VPA-treated group. Collectively, autistic phenotype induced by postnatal VPA exposure caused increased cell proliferation and reduced neural differentiation in rat hippocampus, which could contribute to social deficit and anxiety.

Title: Serum antibody changed in MAOA deficiency autism spectrum disorder mice

Authors: *K. CHEN[1], J. C. SHIH[1,2], C.-S. CHEN[3], F. SUTANDY[3];
[1]Dept Pharmaco & Pharmaceut Sci., Univ. South Calif, LOS ANGELES, CA; [2]Cell & Neurobiology, Keck Sch. of Med., USC, Los Angeles, CA; [3]Grad. Inst. of Systems Biol. and Bioinformatics, Natl. Central Univ., Jhongli City, Taoyuan County, Taiwan

Abstract: Monoamine oxidase A (MAOA) is an enzyme that metabolizes xenobiotic monoamines including serotonin, dopamine and norepinephrine. The MAOA deficient human and knock-out mouse has impairment in social interactions, and autism spectrum disorder phenotype (1, 2). MAOA is highly expressed in digestive system epithelial cells. We suspect the MAOA KO mice may also have abnormal immune response. Here we performed a comprehensive study by using human proteome microarray containing ~17,000 non-redundant human proteins to compare the serum profiles of wild type and MAOA KO mice. Sixteen serum samples from two different groups were collected and probed into the human proteome chip. Twenty six proteins were identified as up or down regulated proteins in the mutant which were most likely corresponded to MAOA related pathways. We further profiled the identified proteins to screen out any protein which might be related to the development of autism. Among them, we were interested on a protein from retinoic acid pathway cellular retinoic acid binding protein 2 (CRABP2). This protein was previously reported for its implication in many neural diseases as its important function in neuron differentiation. Moreover neural differentiation is a critical process which is altered in most autism cases. Based on our current findings we hypothesized that this protein and retinoic acid pathways were the missing gap between MAOA and autism development. Further experiment will be conducted in the near future to clearly demonstrate the role of CRABP2 in MAOA related autism development.
The discovery of changed serum antibody profile in MAOA KO ASD model offered possible application of serum antibody as a diagnostic method for ASD and other neuropsychological diseases.

Title: Mice lacking MMP-9 show stereotypic behaviors, but no social impairment

Authors: *K. Z. MEYZA, A. PUSCIAN, T. LEBITKO, E. KNAPSKA;
Nencki Inst. of Exptl. Biol., Warsaw, Poland

Abstract: Matrix metalloproteinase-9 (MMP-9), known to be involved in regulation of synaptic plasticity, has recently been implicated to play a role in development of autism spectrum disorder (ASD). Increase in its expression in the amniotic fluids has been correlated with the consequent diagnosis with ASD in a population of Danish children (Abdallah et al. 2012) as well as with behavioral impairments in Fragile X syndrome patients. Since the amount of expressed MMP-9 and its activity are crucial for control of learning (and unlearning), which seems to be altered in ASD patients, we suggested that the lack of this enzyme should cause autism-like behaviors in MMP9KO mice. To test that, we used the Intellicage system allowing for observation of place preference learning and reversal without much human intervention. Already at the adaptation level we found that females lacking MMP-9 showed stereotypic bias towards a chosen cage corner, usually observed in mouse models of autism. The MMP9KO males behavior however, was similar to that of WT mice. To test their social behavior we tested the animals in social approach paradigm (3-chambered apparatus) to find that KO mice did not differ from WT in either time spent on the social side of the apparatus, nor in the duration of sniffing an unfamiliar animal during the test session of this paradigm. The lack of MMP-9 seems to affect the stereotypic behaviors and learning abilities rather than social preference.

Title: Transcriptome profiling in Engrailed2 knockout mice reveals convergent molecular pathology associated with ASD

Authors: *P. SGADÒ[1], G. PROVENZANO[1], V. ADAMI[1], E. DASSI[1], G. ZUNINO[1], S. GENOVESI[1], S. CASAROSA[1], Y. BOZZI[1,2];
[1]Ctr. For Integrative Biol. - Univ. of Trento, Trento, Italy; [2]CNR Neurosci. Insitute, Pisa, Italy

Abstract: Genome-wide association studies indicated the human Engrailed2 gene (EN2) as a candidate gene for autism spectrum disorders (ASD). Recent studies showed that En2 knockout mice (En2-/-) represent a suitable animal model to study the neurodevelopmental basis of ASD. En2-/- mice display cerebellar hypoplasia and a reduced number of Purkinje cells, as well as "ASD-related" behaviors, such as decreased attitude to play, spatial learning deficits and increased seizure susceptibility. En2 controls the patterning and neuronal differentiation in the midbrain/hindbrain region, where it is mainly expressed. However, our recent data indicate that En2 is also expressed in the adult hippocampus and cerebral cortex, suggesting that it might also control the function of telencephalic regions. Using qPCR and immunohistochemistry for GABAergic markers, we found that En2-/- mice have a partial loss (about 30%) of GABAergic interneurons in the hippocampus and somatosensory cortex, as compared to WT mice. These anatomical changes are accompanied by a profound alteration of the gene expression profile in the En2-/- forebrain. We compared the cerebellar expression profile with that of the hippocampus using microarray experiments. Based on our statistical criteria we found 842 differentially expressed genes in the cerebellum of En2-/- mice compared to their control littermates. Among these 403 and 439 showed up- and down-regulation, respectively. In the hippocampus we found 862 differentially expressed genes, among those 378 were up-regulated and 484 were down-regulated in En2-/- mice. To validate differential expression we selected 20 genes for qPCR analysis and demonstrate that the expression differences reported by qPCR for the tested genes correlated with the microarray data. To assess the functional consequences of En2 ablation we analyzed enrichment of the differentially expressed genes based on the mouse phenotype database and found for the hippocampus a significant enrichment for "seizure-related" phenotypes. Remarkably, when analyzed specifically for association with autism-related genes of the SFARI repository (sfari.org), the differentially expressed genes showed significant overrepresentation of known autism susceptibility genes both in the cerebellum and in the hippocampus. In details, 18 and 25 of the differentially expressed genes, respectively in cerebellum and in the hippocampus, were present in the SFARI ASD genes.
The molecular evidence we collected suggest that En2 mutation cause alterations in several

pathways associated to ASD, suggesting a prominent role of En2 in the dysregulation of convergent biological pathways in ASD.

Title: Altered synaptic plasticity and abnormal behaviors in Shank3 exon 4-9 mutant mouse model of autism

Authors: *T. C. JARAMILLO, H. E. SPEED, J. REIMERS, Z. XUAN, S. LIU, C. M. POWELL;
Neurol. & Neurotherapeutics, UT Southwestern Med. Ctr., Dallas, TX

Abstract: Shank3 (aka Pro-SAP2) is a multi-domain, synaptic scaffolding protein that organizes glutamate receptors and scaffolding proteins in the postsynaptic density of excitatory synapses. Clinical studies suggest that ~0.5 % of autism spectrum disorder (ASD) cases may involve Shank3 mutations/deletion, suggesting a role for this gene in autism pathogenesis. Patients with Shank3 mutations exhibit deficits in cognition along with delayed speech and repetitive and obsessive/compulsive-like (OCD-like) behaviors. To examine how mutation/deletion of Shank3 might alter brain function leading to ASD, we have created mice with deletion of exons 4-9, corresponding to the ankryin repeat domain, a region implicated in ASD patients with mutations or translocation breakpoints.
Consistent with previous reports, we find that homozygous deletion of exons 4-9 (Shank3e4-9) results in a loss of only the highest molecular weight isoform of Shank3 (Shank3α).

Behaviorally, Shank3e4-9 KO mice displayed increased repetitive grooming, deficits in object recognition learning and memory, abnormal ultrasonic vocalizations, normal coordination on the rotarod, and normal sociability. Biochemical analysis of synaptoneurosome fractions revealed striatum-specific deficits in GluN2B and GluR2/3 subunit expression that coincided with a reduction in NMDAR/AMPAR ratio in excitatory inputs onto striatal medium spiny neurons. There were also reduced levels of Homer1b/c and PSD-95. Furthermore, Shank3e4-9 KO mice displayed reduced hippocampal LTP, enhanced DHPG LTD and normal baseline synaptic transmission. Thus, complete loss of the highest molecular weight isoform of Shank3 in mice is sufficient to induce behavioral deficits loosely analogous to those seen in many patients with Phelan-McDermid Syndrome or ASD. Additionally, biochemical and physiological changes in Shank3-E4-9 mice suggest region-specific roles for the Shank3α isoform in regulating AMPAR and NMDAR subunit localization or expression and function. Our data suggest that replication of phenotypes across laboratories in similar genetic models will ultimately reveal the most robust behavioral phenotypes, the most relevant functional abnormalities, and ultimately the most promising therapeutic targets.

Title: Changes in molecular motors in doublecortin deficient mice

Authors: *X. FU, K. J. BROWN, J. K. JAISWAL, J. S. LIU;
Neurosci., Children's Natl. Med. Ctr., Washington, DC

Abstract: Mutations of the human doublecortin (DCX) gene cause X-linked lissencephaly and double cortex syndrome. The molecular mechanism of DCX effects is not fully understood. As a microtubule-associated protein, Dcx has a novel function in the regulation of molecular motors. Specifically, Dcx is essential for the function of Kif1a, a kinesin-3 motor protein that traffics synaptic vesicles. Because of the severity of the Dcx/Dclk1 phenotype (defects in neuronal migration, axon and dendrite formation), we hypothesized Dcx regulation of motors in addition to Kif1a. We performed a semi-quantitative proteomic analysis of the corpus callosum in mice mutant for Dcx. In axons from mice mutant for Dcx, differences are found in several motor

proteins including dynein, a major motor protein transporting cargo along microtubules towards the minus ends. Further analysis using immunostaining, live imaging, immunoprecipitation, and Western Blotting indicate that Dcx inhibits dynein mediated retrograde transport. Therefore, although Dcx enhances forward trafficking by kinesins, Dcx inhibits retrograde dynein transport. This finding further demonstrates the critical roles of Dcx in motor trafficking and demonstrates why disruption of Dcx leads to abnormal neuronal development.

Title: Cerebellar pathology results in compensatory neural adaptations within cerebellar-prefrontal cortex pathways involved in modulating cortical dopamine release: Relevance to Autism-related behavioral disorders

Authors: E. MCKIMM[1], B. CORKILL[1], D. HECK[2], D. GOLDOWITZ[3], G. MITTLEMAN[1], *C. D. BLAHA[1];
[1]Dept. of Psychology, Univ. of Memphis, MEMPHIS, TN; [2]Dept. of Anat. & Neurobio., Univ. Tennessee Hlth. Sci. Ctr., Memphis, TN; [3]Child and Family Res. Inst., Ctr. for Mol. Med. and Therapeutics, Dept. Med. Genet., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Autism is characterized by at least two neural abnormalities: cerebellar pathology that includes Purkinje cell loss or functional dysregulation as well as compensatory changes in prefrontal cortex (PFC) dopamine (DA) transmission. The inter-relationship between these two abnormalities is unknown. We have previously shown that PFC DA release evoked by electrical stimulation of the cerebellar dentate nucleus (DN) is attenuated in Lurcher (Lc) mutant mice lacking Purkinje cells (Mittleman et al. 2008 Synapse). A similar loss of PFC regulation was also observed in FMR1 mutant mice showing cerebellar neuropathology involving Purkinje cells. In both mutant mice the PFC dysregulation was directly related to disruption in glutamate (GLU) neurotransmission in DN pathways projecting to the PFC via (**1**) the VTA or (**2**) mediodorsal (Thmd) and ventrolateral (Thvl) thalamic nuclei (Rogers et al. 2011 Synapse). Finally we have also shown that there is a decrease in the amount of localized GLU release in these two circuits (McKimm et al. SfN 698.01). Here we investigated the hypothesis that the disruption in GLU

release is accompanied by postsynaptic developmental adaptation in the two circuits mediating PFC dopamine release. We used fixed potential amperometry in combination with carbon fiber electrodes in urethane anesthetized (1.5g/kg i.p.) wildtype and Lc mice. We stimulated the Thmd, Thvl, or the VTA (50 pulses; 50 Hz) and recorded PFC DA release. Results indicated that there was a greater increase in DA release observed in the PFC while stimulating the VTA in Lc mutant compared to wildtype mice (0.087:0.027nA; [$F(1,5) = 15.6$, $p = .01$]. Conversely, no significant differences were seen with Thmd or Thvl stimulation-evoked PFC DA release between the Lc and wildtype mice {[$F(1,4) = 6.85$, $p = .06$]; [$F(1,5) = .03$, $p = .87$]}. These findings suggest that developmental loss of cerebellar Purkinje cells results in a postsynaptic developmental adaptation in the DN-VTA-PFC circuit. This shows that, although local GLU release is reduced in the VTA, DA release in the PFC is enhanced. This result is consistent with a compensatory enhancement of dopaminergic neurotransmission in the VTA to PFC pathway. In the thalamic pathway, despite a reduction in DN-Th-PFC Glu transmission, no observed compensation occurs postsynaptically in the Thmd or Thvl. Considered together, these compensatory changes, or lack thereof, that result in a change in the relative balance between these two circuits modulating PFC DA release may have implications in understanding the cognitive deficits as well as impairments in social reward commonly observed in autism.

S.H., Rome, Italy; [11]Mafalda Luce Ctr. for Pervasive Developmental Disorders, Milan, Italy

Abstract: P-cresol (4-methylphenol) does not derive from human metabolism. It can be absorbed through the skin, GI or respiratory tracts, but its main source consists in gut bacteria (especially some clostridia) able to push the fermentation of tyrosine up to p-cresol. We found elevated urinary amounts of p-cresol in autistic children up to 8 years of age (Altieri et al., Biomarkers 16:252-260, 2011). These initial findings were replicated and extended by measuring total urinary p-cresol and its derivatives p-cresylsulphate and p-cresylglucuronate using HPLC-fluorimetric detection in 33 French autistic children and 33 matched controls. Urinary p-cresol and its derivatives were all significantly elevated in French ASD cases compared to controls ($p<0.05$). This difference was significant in 18 case-control pairs younger than age 8 ($P<0.05$), but not in 15 pairs of older children ($P=0.211$), although two 8-yo children displayed very high amounts. No correlation was found with clinical severity. In another sample including 32 Italian ASD children and 16 controls, we assessed in parallel intestinal permeability using the LA/MA test, presence of Clostridial species and toxinA in the feces, stool habits and recent antibiotic use. No case of gut infection with C. difficile was detected and no correlation was found with intestinal permeability, but a trend with intestinal transit time was detected. Acute behavioral effects were assessed in rodents administering p-cresol 1 mg/Kg (N=4), 10 mg/Kg (N=4), or vehicle (N=4) i.v. to 12 male BTBR mice at P60, using open field, elevated plus maze and object recognition test. Acute p-cresol largely increases time spent in the open arms of the plus maze and decreases exploration of novel objects at the object recognition test (both $P<0.05$), with no effect in the open field. Finally, calcium-imaging experiments using Fluo-4-AM in cultured cortical neurons demonstrate that p-cresol (40.7 mg/L) does not affect resting intracellular calcium concentration, while significantly antagonizing caffeine (20mM)-induced calcium release through ryanodine receptors (-67%; $P<0.001$). Urinary p-cresol is thus elevated in autistic children prior to and including age 8, possibly reflecting slow intestinal transit time and acutely modulating behaviour.

Title: *In vitro* voltage sensitive dye imaging study of a role of NMDA on amygdalar-striatal functional connectivity

Authors: *D. BOHORQUEZ, R. WHITE, K. ZHU, G. CARLSON;
Univ. of Pennsylvanina Perelman Sch. of Med., Philadelphia, PA

Abstract: The amygdala is made up of a number of nuclei that interconnect to many areas of the brain to mediate learning, social interactions, and anxiety. While the anatomical connectivity has been well studied the functional connectivity is not well understood. Strong gamma-band coherence has been found during certain learning tasks between the basal-lateral amygdala (BLA) and striatum. In order to assay functional connectivity between striatal areas medial to the amygdala and the BLA we made coronal slices through the adult mouse brain that captured these areas. These slices were died with voltage sensitive dye and imaged a 1kHz. Following stimulation of the BLA, after the LA, the strongest activity appeared to be the striatal areas directly medial to the BLA. By contrast the central medial amygdala rarely generated robust responses to be either BLA or LA stimulation. This strong striatal response was delayed by 2 to 3 msec consistent with monosynaptic response to the BLA stimulation. To test the ability of this synaptic connection to propagate high frequency activity into the striatum gamma-band bursts were generated in the BLA. These generated both sustained and high frequency ensemble activity in the striatum. In order to explore the role of NMDA receptors in these components AP5 and D-cyclo-serine was applied. Surprisingly, AP5 had very little effect on the response, yet D-cyclo-serine appears to reduce activity. These data suggest a NMDA receptor dependent role on inhibitory components modulating amygdalar activity.

Title: Social behaviors can be assessed with computer vision in mouse models of disease in a home cage environment

Authors: *T. HANANIA, P. KABITZKE, M. MAZELLA, I. FILIPOV, V. ALEXANDROV, D. BRUNNER;
PsychoGenics Inc., TARRYTOWN, NY

Abstract: The assessment of social behavior has become critical for the phenotyping of animals models of autism and schizophrenia. Scoring of videos is both time consuming and subjective, causing inter-observer and between-studies variability, thus emphasizing the need for automated scoring.
Computer vision classification of social behavior is, on the other hand, challenging, due to the frequency of occlusions and contacts between mice. We have solved the problem of occlusion with sophisticated computer vision techniques and individual tags. Careful choice of algorithms also allows us to analyze videos in almost real-time, by minimizing CPU time. Our choice of lighting and camera sensitivity also allow us to track mice during the dark circle and to score their behavior 30 times a second, 24 hours a day, up to 6 days continuously. Assessment of social behavior in a non-stressful environment can also produce qualitatively different phenotypes, as the behavior is not confounded with anxiety or a response to manipulation. We will present data obtained with mouse models of autism, that demonstrate the utility of the system.

Title: Emotional pertubations in an environmentally induced animal model of autism

Authors: *A. BANERJEE, J. A. LUONG, S. K. LELLA, B. L. SAULS, C. ENGINEER, M. P. KILGARD, J. E. PLOSKI;
Behavioral and brain science, Univ. of Texas Dallas, Richardson, TX

Abstract: Autism Spectrum Disorders (ASD) are complex neurodevelopmental disorders characterized by core symptoms including repetitive behavior, impaired social interactions and deficits in social communication. Apart from these core symptoms, a significant number of ASD individuals display maladaptive emotional responses. For example numerous studies indicate that ASD individuals display higher levels of anxiety and some studies indicate that ASD individuals are impaired in their ability to be fear conditioned. Therefore we sought to further examine innate fear and emotional learning utilizing an environmentally induced animal model of ASD. This model focuses on progeny from pregnant rats exposed to the known teratogen, valproic acid (VPA) on day 12.5 of gestation. Specifically we exposed dams to either one of two different doses of VPA (500 and 600 mg/kg) or vehicle on day 12.5 of gestation. Resultant progeny at 60 days of age were examined for innate fear and changes in locomotion using an open field test. We then auditory fear conditioned these rats to a 5 kHz 75 dB tone. Our preliminary data indicates that embryonic exposure to VPA, at both doses enhances anxiety as measured as decreased center entries in the open field test, with no changes in overall locomotion. Animals exposed to 500 mg/kg VPA displayed normal acquisition of fear conditioning, but exhibited reduced extinction of fear memory - data consistent with previously published reports. However we observed that rats exposed to 600 mg/kg of VPA exhibited a significant reduction in acquisition of fear conditioning. To determine if the decrease in fear conditioning was due to a sensory deficit, we examined pain perception and hearing in VPA exposed rats. VPA exposed rats exhibited normal pain sensitivity in a hot plate test and exhibited normal hearing to a 5 kHz, 75 dB tone as determined by normal spike firing within the auditory cortex during exposure to 5kHz tones presented at varying degrees of loudness up to 75 dB. Collectively these data indicated that the reduced acquisition of fear learning is not likely due to sensory deficits, but rather due to deficits in learning. To examine the molecular basis of VPA induced impairment in fear learning in animals exposed to VPA (600 mg/kg), we performed whole genome gene expression analysis using DNA microarrays on amygdala RNA from rats exposed to VPA and vehicle. The microarray data indicated that VPA exposed rats may have dysfunctional glutamatergic signaling within the amygdala. We are currently investigating the

hypothesis that deficits in glutamatergic signaling underlie at least in part the impairment in emotional learning in animals exposed to VPA.

Title: Altered learning and novelty-seeking behavior in adult mice lacking the neuropilin 2 gene

Authors: *M. W. SHIFLETT[1], M. GAVIN[2], T. S. TRAN[2];
[1]Psychology, Rutgers Univ. Newark, NEWARK, NJ; [2]Dept. of Biol. Sci., Rutgers Univ., Newark, NJ

Abstract: The proper formation of neural connectivity depends critically upon the spatially and temporally coordinated regulation of neuronal morphology, and is essential for the precise and complex functions of neural networks controlling appropriate behavior in the animal. However, a large gap in knowledge exists between the molecular mechanisms controlling neuronal morphogenesis and synapse formation to the change in behavior output. Class 3 secreted semaphorins and their neuropilin and plexin receptors are implicated in a large number of neural developmental events, including axon guidance, dendritic branching, excitatory synapse formation, and target selection. Previously, we showed that the secreted semaphorin Sema3F and its Npn2/PlexA3 receptor complex are required for normal hippocampal and layer 5 cortical neuron dendritic spine morphology and excitatory synapse transmission. Here, we investigate the effects on cognition and behavior of altered semaphorin signaling, by testing mice deficient in the gene encoding Npn2. We found that Npn2 knockout mice exhibit altered behavior on novelty-seeking tasks. Specifically, Npn2-/- mice showed no preference for novel social and non-social stimuli as compared with wild type age-matched littermate controls. Furthermore, Npn2 knockout mice were impaired in an operant discrimination learning task, suggesting a fundamental impairment in memory formation. Additionally, Npn2 null animals exhibited

increased anxiety-related behaviors in the open field and tail-suspension tests. We found no effects of the knockout on locomotor behavior or olfactory habituation/dishabituation, indicating intact sensorimotor processing in Npn2-/- animals. We are currently expanding our behavioral tests to analyze Sema3F and PlexA3 knockout mice. Thus, our results support novel roles for secreted semaphorin signaling in controlling complex behaviors in adult mice and underscore the necessity of understanding the mechanisms of how changes in neuronal morphology and connection may lead to altered complex behavior output.

Title: Visual preference for images of humans in non-human primates; relevance to primate models of autism

Authors: D. DZIOBEK[1], S. ZHANG[2], J. ASHE[1], *X. LU[3];
[1]Neurosci., Univ. of Minnesota, Minneapolis, MN; [2]Univ. of Minnesota, Biomedical Engineering, MN; [3]Brain Sci. Ctr., VA Med. Center, Minneapolis, Minneapolis, MN

Abstract: Autism is a devastating neurological disorder of unknown cause, unclear pathogenesis and without an effective treatment that appears to be increasing in prevalence. Although there are many animal models of this disorder particularly in rodents, the relevance of these models to a human disease that is defined by abnormal social interaction is debatable. In an effort to characterize natural social behaviors in the non-human primate that might be targeted in developing a primate model of the disorder, we studied preferences for different classes of visual images: (i) neutral non-animate objects, (ii) images of familiar foods, and (iii) images of human faces. We trained non-human primates on a task in which they were presented two visual images simultaneously, and are asked to choose between them. First they were required to hold their gaze on a central fixation point for 500-700 ms after which were presented two images located at either 0 degree (right) and 90 degree (up) positions, or at 180 degree (left) and 270 degree (down) positions but maintained fixation on the center point for another 500-700 ms (delay). After this delay time, the center fixation point disappeared (Go signal) and the subject made a saccade to one of the images and to hold on the image target for 300 ms to receive the reward. The eye movements were monitored continuously and the subjects were rewarded regardless of

which image they chose. We found that, when presented with two neutral inanimate images (e.g. two different chairs), the monkey showed no preference (51% vs. 49%). When images of a human face was paired with either a neutral object (e.g. palm tree or chair) and a familiar food (e.g. banana or peanuts), the monkey preferred the face in more than 90% of trials. There were no clear differences in preferences for familiar (experimenters) or unfamiliar (George W. Bush) faces relative to the other classes. Furthermore, in addition to choice preference, the animals had shorter reaction time and eye movement time to human faces. Our data suggest that the preference of non-human primates for human faces, even when the competing object was a familiar food, is driven by considerations of social cognition that are so prominent in humans. We believe that this natural tendency of non-human primates to prefer images of other primates could be used to probe autistic behavior in monkey models of autism.

Title: Reexpression of Mecp2 in GABAergic neurons is sufficient to rescue the effects of global Mecp2 deletion

Authors: *K. M. URE, H. LU, E. SZTAINBERG, H. ZOGHBI;
Baylor Col. of Med., Houston, TX

Abstract: Rett syndrome is a devastating neurological disorder affecting predominantly young girls. It is characterized by the loss of acquired milestones, including language, and the development of repetitive hand movements, ataxia, breathing abnormalities, seizures, and autistic-like features. The disease is caused by mutations in MECP2, which encodes a chromatin remodeling protein that binds methylated CpGs. Mecp2-null male mice and heterozygous female mice replicate most of the phenotypes seen in human patients. Interestingly, deletion of Mecp2 only from neurons expressing vesicular inhibitory amino acid transporter (Viaat), a specific marker of inhibitory neurons, replicates most of the clinical symptoms of Rett, including ataxia, repetitive behaviors, breathing abnormalities, and learning and memory deficits, likely due to reduced GABA signaling. This finding highlights the critical role of proper GABAergic neuronal function in the pathogenesis of Rett syndrome and points to the inhibitory circuitry as a potential target for therapeutic intervention. To test this, we genetically reactivated Mecp2 expression in Viaat-expressing neurons using a conditional allele of Mecp2 engineered to contain a flox-stop-flox locus upstream of the Mecp2 coding region, resulting in the generation of mice that express

MeCP2 exclusively in GABAergic neurons. These animals were evaluated along with all relevant controls (Mecp2 null, Viaat-Cre alone, and wildtype). Both male and female “rescue” mice showed normalized body weight and improvement in ataxia, apraxia, learning and memory, and social interaction, along with significantly extended lifespan and some inhibitory signaling normalization. However, the rescue mice did not exhibit a full rescue of all Mecp2-deletion phenotypes; they had noticeable tremor, sensorimotor gating defects (as measured by prepulse inhibition), and died prematurely, with 50% of male rescue mice dying by 40 weeks of age. Furthermore, there was some loss of behavioral benefits later in life. These findings suggest that modulation of GABAergic function in the Rett brain may be a viable therapy option, particularly at early stages of the disorder; to this end we have begun pharmacological studies in the mouse model of Rett syndrome to determine the extent of benefit from enhancing GABAergic signaling.

Title: Rett Syndrome like phenotypes in the R255X Mecp2 mutant mouse are rescued by MECP2 transgene

Authors: *M. R. PITCHER[1,2], A. FISHER[3], N. C. SCHANEN[3], J. L. NEUL[1,2];
[1]Baylor Col. of Med., Houston, TX; [2]Jan and Dan Duncan Neurolog. Res. Inst., Houston, TX; [3]Nemours Biomed. Res. Dept., Wilmington, DE

Abstract: Over thirty percent of Rett Syndrome (RTT) cases are due to nonsense mutations in *MECP2*, where a change in nucleotide sequence leads to a premature stop codon in the mRNA transcript. One strategy to overcome disease-causing stop mutations is treatment with nonsense suppressing read-through compounds, such as gentamicin, which reduce the stringency and fidelity of ribosomes translating mRNA messages to allow expression of full length proteins from a mutated gene. To determine if this strategy may be useful in RTT we characterized a new mouse model of RTT that has a knock-in nonsense mutation (p.R255X) in the *Mecp2* locus (*Mecp2*$^{tm1.1Irsf/J}$). *Mecp2* is a four exon gene that encodes two functional domains: the methyl binding domain from exons 3 and 4 and the transcription repression domain in exon 4. Because

the R255X mutation is located in the transcription repression domain of *Mecp2*, it is possible that a dominant negative DNA binding truncation product could be produced from the disease allele. To determine if the truncated gene product acts as a dominant negative allele, we genetically introduced an extra copy of *MECP2* via a *MECP2* transgene. This allows us to determine whether adding a wild-type version of MeCP2 is sufficient to rescue phenotypic abnormalities in *Mecp2*$^{tm1.1Irsf/J}$ mice, or whether the truncated allele has a dominant negative effect insurmountable by a wild-type copy. *Mecp2*$^{tm1.1Irsf/J}$ mice have phenotypes nearly identical to complete null animals: decreased weight early in life, decreased heart rate late in life, abnormal breathing phenotypes, poor motor coordination, and decreased survival time. The addition of the *MECP2* transgene to *Mecp2*$^{tm1.1Irsf/J}$ mice abolished the phenotypic abnormalities and resulted in near complete rescue. This provides a proof of concept that this mutation is amenable to read-through therapy. Future studies will include pharmacokinetic and efficacy preclinical trials in the R255X model using read-through compounds that are currently in clinical trials for peripheral indications. We hope to demonstrate that read-through therapy is a viable treatment option for neurological disease caused by nonsense mutations.

Title: A comparison of cortical and cerebellar gene dysregulation in three MeCP2 mutant mouse models

Authors: *G. M. JENTARRA, B. CHAVIRA;
Biochem., Midwestern Univ., Glendale, AZ

Abstract: Mutations in the MeCP2 gene, encoding methyl-CpG binding protein 2, are associated with the neurodevelopmental disorders Rett syndrome and X-linked mental retardation (XLMR). This gene has various functional domains including the N-terminal methyl-CpG-binding domain (MBD) and the C-terminal transcriptional repressor domain (TRD). MECP2 is believed to act as both a transcriptional activator and a repressor of the expression of other genes. In order to explore the results of compromised or lost function of one or both of these domains, gene expression in three MeCP2 mutant mouse models was examined using pathway specific qPCR

array plates. The array chosen examined the expression of genes involved in forming the receptors for the major neurotransmitters in the brain. The MeCP2 mutant models used included the A140V model, which replicates a MeCP2 point mutation in the MBD associated with XLMR in males; the 308/y model, which has a C-terminal truncation deleting the TRD of MeCP2; and the "Bird" MeCP2-null model which does not produce functional MECP2 protein. Arrays were run on both cortical and cerebellar brain tissue from 6 week old male mutant mice and their wild type littermates. The data indicate that genes involved in forming the receptors for GABA, acetylcholine, and dopamine are commonly dysregulated due to MeCP2 mutations. These neurotransmitters have been previously implicated in Rett syndrome. In addition, the study identified dysregulation of genes encoding receptors for tachykinin, neuropeptide Y, somatostatin and serotonin. The results of this study demonstrated substantial changes in gene expression which varied based on the brain region sampled (cortex versus cerebellum) and on the specific mutation.

Abstract: It becomes increasingly recognized that changes in synaptic transmission and/or neural network properties are regional- and circuitry-specific with various neurological

conditions. This feature poses a huge challenge for using patient-specific induced pluripotent stem cells (hiPSCs) to model neurological disorders, because currently little could be done to control the context of the various neural network formed in such “disease-in-a-dish” models. Here, we report that neurons derived from human embryonic stem cells (hESCs) and Rett syndrome (RTT) isogenic hiPSCs exhibit variable spontaneous postsynaptic currents and variable ratios between excitation-inhibition from culture to culture. Intentional alterations of neural circuitry contents using a ventralizing agent changed neural transmission phenotype, suggesting a circuitry-specific nature of such phenotype. In contrast, cell-intrinsic electrophysiological and morphological properties of RTT neurons demonstrate consistent changes, independent of the type of circuitries formed.Our findings demonstrate that “disease-in-a-dish” models using hiPSC-derived neurons, while may capture cell-intrinsic phenotypes of diseased neurons, could be rather challenging for assessing neural-circuitry-dependent phenotypes.

Title: Genetically engineered human pluripotent stem cell model of Rett Syndrome

Authors: *Y. LI, R. JAENISCH;
Whitehead Institute, MIT, Cambridge, MA

Abstract: The advent of human pluripotent stem cell technology, including that of embryonic stem cells and induced pluripotent stem cells, has opened up a new avenue in human disease

modeling. A crucial limitation in using these patient-specific pluripotent stem cells is the lack of genetically-matched controls. Here we report the generation of isogenic human pluripotent stem cell model of Rett Syndrome by genetically modifying the MECP2 gene. Using TALEN-mediated gene targeting, we have introduced loss-of-function mutation into the MECP2 gene, and generated hemizygous, heterozygous and homozygous null cells. These isogenic human pluripotent stem cells were differentiated into neural progenitor cells as well as mature neurons and astrocytes. We showed that neurons derived from MECP2 null pluripotent stem cells have smaller soma and reduced neurite arborization compared to their isogenic controls. Further analyses revealed that MECP2 null neurons bare key molecular, cellular and physiological features of Rett Syndrome. In summary, our results demonstrate the feasibility of TALEN-mediated gene targeting in generating an in vitro model of human neurodevelopmental disorder. By dissecting disease-related phenotypes in MECP2 null neurons, we hope to investigate disease mechanism, and develop therapeutic strategies that ameliorate these phenotypes in vitro and in vivo.

Title: *In vivo* testing of a self-complementary AAV9 construct expressing a codon-optimized Mecp2 transgene in a preclinical model of Rett Syndrome

Authors: *V. MATAGNE, L. VILLARD, J.-C. ROUX;
INSERM UMR_S910 - Aix-Marseille Univ., Marseille, France

Abstract: Rett syndrome (RTT) is an X-linked neurodevelopmental disorder primarily affecting CNS functions but also peripheral functions. There is currently no cure for the disease and treatments available are aimed at improving RTT symptoms. Most RTT cases are due to mutation in methyl CpG binding protein 2 (MECP2), whose main function is that of a global transcriptional repressor.
The recent findings that reactivation of Mecp2 rescued adult diseased RTT mice not only indicates that MECP2 is needed for normal adult function (Robinson et al, Brain 2012) but also that gene therapy might be beneficial for RTT patients, even after the disease has started. Proof

of principle that gene therapy was beneficial in a RTT mouse (Mecp2-null mice) has been recently reported by Gadalla et al (Mol Ther, 2013). The authors showed that benefits of the treatment were highest when the virus was directly administered in the brain of newborn mice, while a more translational approach (i.v. injection in young adult Mecp2-null sick mice) yielded minimal improvement.
In order to try and improve vector delivery and expression, we designed two plasmid constructs expressing GFP (control virus) or a codon-optimized version of Mecp2 (termed MCO) under the regulation of the mouse Mecp2 promoter (pMecp2) and confirmed their efficacy in vitro by transfecting NIH/3T3 mouse fibroblasts. Western blot showed that transfection with the MCO plasmid resulted in a twofold increase in MECP2 protein expression compared to cells transfected with a plasmid expressing the endogenous mouse Mecp2e1 gene under the control of a CMV promoter (6.45±1.1 for MCO vs 3.4±0.8 for Mecp2e1, in arbitrary units, ImageJ densitometric analysis). AAV9 viruses carrying either plasmid constructs (pMecp2-GFP or pMecp2-MCO) were produced and their efficacy was tested in primary mixed neurons/glia cultures from male Mecp2-null mice and their littermate controls. DIV10 primary cultures were infected at a multiplicity of infection (MOI) of 10,000:1 and infected cells were identified by immunocytochemistry. Results showed that the pMecp2 promoter directed the expression of GFP or MCO mostly in neuronal cells (TUJ1+ cells).
As reported by other groups, we found that the AAV9 control virus crosses the BBB after i.v. injection (through the tail vein) in wild-type mice and principally transduce neuron-like cell types throughout the brain. Our next experiments will determine whether administration of the scAAV9-MCO virus to a RTT mouse model (Mecp2-null mice) is able to rescue the neurological symptoms seen in these mice.

Title: Interneuron-specific mecp2 reactivation rescues rett syndrome phenotypes

Authors: ZHOU[1], W. WU[2], X.-M. LI[3];
[1]Inst. of Neuroscience, Zhejiang Univ., Zhejiang, China; [2]The children's hospital, Zhejiang Univ. Sch. of Med., Hangzhou, China; [3]Inst. of Zhejiang Univ., Hangzhou, China

Abstract: Rett syndrome (RTT) is considered as a neurodevelopmental disorder caused by mutation of X-linked *MeCP2* gene which encodes methyl CpG binding protein 2 (MeCP2) that regulates gene transcription. MeCP2 null or conditional mutant mice exhibit many aspects of Rett syndrome phenotypes. However, the underlying mechanism is still to be uncovered. Here we reactivated the MeCP2 in GABAergic neurons specifically by crossing MeCP2-Stop mice with Dlx5/6-Cre mice. Mice with the reactivated MeCP2 showed improvement in body weight, life span, locomotor ability, coordination, anxiety, social ability, and learning and memory compared to non-rescue MeCP2-Stop mice. In conclusion, GABAergic neurons play an important role in RTT pathogenesis by regulating the expression of some genes that may contribute to the development of new therapy for RTT.

Title: VEGF inhibition as a potential treatment for FXS neocortical vasculature abnormalities

Authors: *A. BELAGODU, R. GALVEZ;
Univ. of Illinois Urbana-Champaign, Urbana, IL

Abstract: Fragile X syndrome (FXS) is the most common form of inherited mental retardation affecting roughly 1:3,600 males and 1:8,000 females. FXS is primarily caused by the transcriptional silencing of the *FMR1* gene which encodes for Fragile X Mental Retardation Protein (FMRP). Recent analyses from our laboratory have demonstrated abnormal vasculature density in a FXS mouse model (Galvan & Galvez 2012). One of the most prominent regulators of vasculature grow is the vascular endothelial growth factor (VEGF). VEGF expression has been shown to be directly correlated to the amount of vasculature. Various behavioral manipulations that increase brain blood vessels, such as enriched rearing and exercise, also increase VEGF expression. Likewise pharmacologically decreasing VEGF expression results in

decreased vasculature. These analyses strongly suggest that altered VEGF expression is a possible cause for the abnormal FXS vasculature phenotype. In support of this assertion our recent preliminary data has demonstrated that VEGF is over-expressed in the neocortex of adult FXS mice. To potentially alleviate this FXS vasculature phenotype the following study used the VEGF antagonist, bevacizumab. Bevacizumab is an anti-cancer medication that has been used to decrease vasculature on tumor cells. It is a humanized monoclonal antibody which binds to VEGF-A and all its isoforms, preventing it from binding to the VEGF receptor. To block VEGF activity 5mg/kg of bevacizumab was injected IP into PND 60 and 11 month old FXS and wild type (WT) mice every other day for 10 days. Blood vessel density in the visual cortex was then examined. Our findings demonstrated that bevacizumab could be used to reduce neocortical vasculature and as a potential treatment for the vasculature phenotype in FXS. Subsequent analyses will need to determine the cognitive and behavioral implications of bevacizumab treatment in FXS.

Title: Electrophysiological characterization of iPSC-derived neurons from Angelman syndrome and Dup15q autism patients

Authors: ***J. J. FINK**, K. A. BOLDUC, T. M. ROBINSON, E. S. LEVINE;
Neurosci., Univ. of Connecticut Hlth. Ctr., Farmington, CT

Abstract: Individuals with a deletion of chromosome 15q11-q13 suffer from Angelman syndrome (AS), a neurogenetic developmental disorder characterized by intellectual disability, ataxia, absent speech, and seizures. The specific gene that is responsible for AS encodes the ubiquitin protein ligase UBE3A. Interestingly, individuals with a duplication of the same

chromosomal region suffer from a form of autism known as 15q duplication syndrome (dup15q). In both syndromes, alterations in synaptic signaling and plasticity appear to play a critical role in the disease phenotype, but the relevant downstream targets of UBE3A are unknown. The discovery of genomic reprogramming of human somatic cells into induced pluripotent stem cell (iPSC) lines provides a novel way to model human diseases with complex genetics. We are using electrophysiological approaches to examine synaptic activity and intrinsic properties of iPSC-derived neurons from AS and dup15q patients, as well as control subjects. After six weeks of in vitro development, a low level of spontaneous synaptic activity was seen in neurons from all genotypes, with no significant difference in the frequency or amplitude of synaptic events across genotype. However, by twelve weeks in vitro, control neurons displayed a dramatic increase in the frequency of synaptic events, which was significantly greater than the frequency in both AS-derived and dup15q-derived neurons, suggesting an increase in synapse number and/or release probability in the control neurons. There was no significant difference in mean amplitude across genotype. We also examined activity-dependent synaptic plasticity using a protocol to enhance NMDA receptor activation and increase cAMP levels. In neurons derived from a control subject, 7/10 cells showed a long-term increase in the frequency of spontaneous synaptic events, with no change in mean amplitude. We are currently exploring potential differences in synaptic plasticity in AS and dup15q-derived neurons. Overall, these approaches may prove useful for identifying novel targets for drug discovery and for screening potential therapeutics aimed at reversing the language and cognitive impairments as well as the seizures and movement disorders associated with Angelman syndrome and autism.

Title: Genetic studies to gain insight into the function of the MeCP2 domains *in vivo*

Authors: *L. HECKMAN[1,2], H. Y. ZOGHBI[1,2,3];
[1]Jan and Dan Duncan Neurolog. Res. Inst., Houston, TX; [2]Mol. and Human Genet., Baylor Col. of Med., Houston, TX; [3]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: Rett syndrome (RTT) is a debilitating neuropsychiatric disorder caused by mutations in the X-linked methyl-CpG binding protein 2 gene, which encodes for a protein with the same name (MeCP2). Many of the RTT-causing mutations create a truncating null allele, suggesting that RTT is due to a loss of MeCP2 function. Interestingly, overexpression of MeCP2 due to duplications in Xq28 also causes a progressive neurological syndrome that shares many features with RTT. Studies in mice that either lack (RTT model) or express 2X MeCP2 (duplication model) reveal that the loss and gain of MeCP2 has opposing effects on excitatory synapses and gene expression, suggesting that the duplication causes the disorder by a "hyperfunction" mechanism. However, the challenge has been to understand exactly what function of MeCP2 is being exaggerated when it is overexpressed. Traditionally, MeCP2 was believed to be a transcriptional repressor, yet gene expression data from animal models does not support this model. Newer hypotheses proposed that MeCP2 dampens transcriptional noise, such that in its absence, increased basal transcription leads to decreased expression of neuronal genes. This model, however, does not quite explain why doubling the protein will enhance expression of activity dependent neuronal genes. Another hypothesis proposes that overexpression of MeCP2 might titrate co-repressors, thus resulting in an increase of gene expression. To determine if DNA binding by the methyl-CpG-binding domain (MBD) is necessary for the neuronal dysfunction resulting from MeCP2 overexpression, I have generated mice that overexpress MeCP2 alleles with three different RTT-causing mutations: T158M, which reduces methyl-CpG binding, R111G, which abolishes methyl-CpG binding without affecting the structure of the MBD, and R306C, which lies within the transcriptional repression domain (TRD). Transgenic mouse lines that express each allele at levels similar to endogenous levels have been generated thus allowing me to study if doubling MeCP2 levels with an allele that either compromises DNA binding activity or one that is beyond the MBD are consequential. Behavioral, physiological and molecular studies of these alleles are ongoing both in the context of overexpression and in a MeCP2 null background. These models promise to provide new insight into the mechanism by which MeCP2 overexpression leads to neurological dysfunction.

Title: Characterization of cortical neuron defects in Fragile X mice

Authors: *A. AHARON, Y. ZUO;
MCD Bio, Univ. of California Santa Cruz, Santa Cruz, CA

Abstract: Fragile X syndrome (FXS) is the most common form of genetically inherited mental retardation. It is caused by the transcriptional silencing of the FMR1 gene that encodes for fragile X mental retardation protein. One hallmark of disease is the abundance of immature dendritic spines in cortical pyramidal neurons. This abnormality has been found in various brain regions in the fixed tissue of human FXS patients, as well as in FMR1 knock out (KO) mice (a mouse model of FXS). So far, most studies concerned with the spine phenotype in FXS have been focused on adult knockout mice, while heterozygous mice continue to go unstudied. Furthermore, it remains unclear how this abnormal spine phenotype progresses during the course of development, and exactly how different neuronal cell types are affected in the diseased brain has yet to be discovered. In this study, we set out to explore these questions by crossing FMR1 KO mice with thy1-GFP-M line mice, a line of mice sparsely labeling individual pyramidal neurons with green fluorescent protein. We then analyzed the neuronal morphology and spine density in layer V pyramidal neurons in the cortex of the wild type (WT), FMR1 heterozygous and FMR1 KO mice. We found that, at 1 month of age, the spine density of apical dendrites is comparable between FMR1 KO, heterozygous mice and their WT littermates. However, FMR1 KO and heterozygous mice did not show normal spine pruning during adolescent development, resulting in a significantly higher (~60%) spine density compared to WT mice at 4 months of age. Currently we are investigating more developmental ages to determine when spine abnormality first appears, we are also studying the variation in different cortical regions and cell types.

Title: Mecp2-null mice displayed possible endogenous compensatory mechanisms in defective neurotransmitter systems

Authors: *M. F. OGINSKY, W. ZHONG, C. M. JOHNSON, N. CUI, C. JIANG;
Biol., Georgia State Univ., Atlanta, GA

Abstract: Rett syndrome (RTT) is an autism-spectrum disorder caused by mutations to the X-linked gene, methyl-CpG binding protein 2 (MeCP2). MeCP2 binds to methylated DNA to regulate transcription. Knockout of this gene in mouse models leads to abnormalities in dendritic formation, intrinsic membrane properties, synaptic transmission and neurotransmitter-synthesizing enzyme expression, which may underlie the development of RTT. Although many systems are affected by mutations in the *MECP2* gene, it is possible that the body may develop certain compensatory mechanisms to alleviate the abnormalities. The norepinephrine (NE) system originating mostly in the locus coeruleus (LC) is defective in RTT and *Mecp2*-null mice. LC neurons are NE-ergic and are subject to modulation by GABA and Acetylcholine (Ach). The relationship among these modulators provides a good system to test our potential compensatory hypothesis. Therefore, we performed studies of neurons in the LC area in WT and *Mecp2*-null mice. The $GABA_A$-ergic IPSC frequency was attenuated by a nicotinic receptor antagonist and this attenuation was greater in *Mecp2*-null mice. The amplitude did not change suggesting presynaptic alterations in nicotinic receptors. With tissue micropunctures from the LC region, the expression of nicotinic receptors was analyzed with qPCR. The largest nicotinic receptor expression levels were for the α3 and α4 subunits in wild-type littermates. The expression of these subunits was decreased by >40% in *Mecp2*-null mice. The α7 and β2 nicotinic receptors subunits that were expressed in low levels in the wild-type were upregulated in the *Mecp2*-null mice. These data suggest that although the *Mecp2* disruption causes a decrease in α3 and α4 subunits, LC neurons appear to be able to compensate for the defects by increasing α7 and β2 expression. This may lead to an increase in $GABA_A$-ergic synaptic transmission that is deficient in *Mecp2*-null mice. The presence of such endogenous compensatory mechanisms may allow novel medical intervention to prevent advancement of the disease.

Title: Neocortical developmental vasculature abnormalities in a mouse model of fragile X syndrome

Authors: S. A. FLEMING, *R. GALVEZ;
Psychology, Univ. of Illinois, Urbana-Champaign, Urbana, IL

Abstract: Fragile X Syndrome (FXS), the most common form of inherited mental retardation, is caused by the transcriptional silencing of the fmr-1¬ gene, which codes for the Fragile X Mental Retardation Protein. The syndrome is accompanied by intellectual disability, autistic-like behaviors, and a variety of physical abnormalities. The most prominent neuronal abnormality is the abundance of long, thin, immature dendritic spines. Studies have also demonstrated that boys with FXS have abnormal cerebral blood flow. Furthermore, recent analyses from our laboratory have demonstrated a lack of age-induced blood vessel density (BVD) plasticity in middle-aged mice with FXS (Galvan & Galvez 2012). During development neocortical regions establish neuronal connections necessary for normal cognition and neuronal function. Abnormal vasculature growth during these critical developmental periods would alter proper neuronal development causing or exacerbating many of the neuronal and cognitive abnormalities associated with FXS. The following study set out to characterize BVD in the visual neocortex of mice with FXS during development. Wildtype (WT) and FXS mice were sacrificed at postnatal dates 10, 20, 35, 60. Neocortical sections were then stained for collagen IV, a protein found in the lumen of blood vessels. Once stained, stereological techniques were used to characterize BVD in the visual neocortex of FXS and WT mice. Our findings demonstrate that FXS exhibit abnormal BVD compared to WT mice during development. Such analyses will provide vital insight into factors contributing towards the anatomical and cognitive abnormalities observed in FXS.

Title: Roles of MeCP2 in the autonomic nervous system

Authors: *T.-W. HUANG[1], J. L. NEUL[2];
[1]Neul Lab., Program in Developmental Biology, Baylor Col. of Med., Houston, TX;
[2]Departments of Pediatrics - Neurol., Baylor Col. of Med., Houston, TX

Abstract: Rett syndrome (RTT) is an X-linked neurodevelopmental disorder associated with loss of communication and purposeful hand skills as well as several autonomic deficits. These autonomic problems may contribute to the sudden death observed in a fraction of people with RTT. Mutations in the gene encoding Methyl-CpG-binding protein 2 (MECP2) cause 95% of RTT cases, and mice lacking MeCP2 function exhibit the pathological features similar to RTT patients.

Removing MeCP2 from brainstem and spinal cord in mice causes early lethality and autonomic phenotypes including decreased heart rate and abnormal respiratory response to hypoxia. In addition, re-expressing MeCP2 within the region is sufficient to rescue these phenotypes. The brainstem is known to contain neural circuits critical for the regulation of autonomic function. To determine which neuronal circuits require MeCP2 for normal hypoxic respiratory response and survival, Cre/LoxP system is used to remove or re-express MeCP2 in specific regions that are known to be important for the control of breathing.

Using transgenic mice express Cre recombinase in the HoxA4 domain; MeCP2 is removed from the caudal medulla, spinal cord, and peripheral nervous system (PNS). The conditional knockout mice showed abnormal motor functions and early lethality, but had normal heart rate and hypoxic breathing response. In addition, MeCP2 expression solely within the HoxA4 domain is sufficient for the survival of rescued animals. To examine whether restored MeCP2 expression in PNS is related to the rescued phenotypes, Sox10-Cre transgenic line was used to restore MeCP2 expression in PNS and oligodendrocytes. Animals expressing MeCP2 in the Sox10 domain continued to have poor motor coordination, abnormal breathing, and early lethality. The results suggested that MeCP2 expression in caudal medulla and spinal cord is critical for the motor coordination and survival, but MeCP2 function within the PNS or oligodendrocytes isn't. MeCP2 expression in HoxA4 or Sox10 domain did not rescue the respiratory hypoxic response. To further determine the regions require MeCP2 for the breathing control, MeCP2 expression was restored in two anatomical regions known to be important nodes for the chemoreflex breathing control circuit, the nucleus tractus solitarii (NTS) and the retrotrapezoid nucleus (RTN), by using Phox2b-Cre transgenic line. Phox2b-Cre rescued animals showed normal breathing response to hypoxia but still display early lethality. These results indicate that MeCP2 expression in NTS and RTN is important for the chemoreflex pathway, and suggest that abnormal breathing response to hypoxia may not relate to the early lethality.

Title: Palmitoylation-dependent cdkl5-psd95 interaction regulates synaptic targeting of cdkl5 and synaptic transmission

Authors: *Z.-Q. XIONG, Y.-C. ZHU, D. LI;
Inst. Neurosci, Shanghai, China

Abstract: The X-link gene cyclin-dependent kinase-like 5 (CDKL5) is mutated in patients with severe neurodevelopmental disorders including an early-onset variant of Rett syndrome. The expression of CDKL5 is developmentally regulated and enriched in the brain. Our recent studies have shown that CDKL5 plays important roles in neuronal development such as neurite growth and dendritic spine morphogenesis. The postsynaptic scaffolding protein PSD-95 is a major palmitoylated protein in neurons and its synaptic targeting depends on palmitoylation. We find that PSD-95 interacts with CDKL5 in a palmitoylation-dependent fashion and regulates its targeting to excitatory synapses. Interestingly, certain disease-associated mutations which abolish this interaction reduce synaptic localization of CDKL5. Moreover, disruption of this interaction diminishes synaptic targeting of CDKL5 and inhibits dendritic spine growth. Thus, our findings reveal an unexpected role of palmitoylated PSD-95 in synaptic targeting of CDKL5, which may represent a novel mechanism for protein trafficking. These results may also provide insights into the pathogenesis of CDKL5-related disorders.

Title: Single-molecule imaging of PSD-95 mRNA translation in dendrites reveals its dysregulation in a mouse model of fragile X syndrome

Authors: *M. F. IFRIM, G. J. BASSELL;
Cell Biol., Emory Univ., Atlanta, GA

Abstract: Fragile X syndrome (FXS) is caused by the loss of the fragile X mental retardation protein (FMRP), an RNA binding protein that regulates translation of numerous target mRNAs. Deficiency of FMRP in a mouse model of FXS, leads to increased basal translation rates of many FMRP target mRNAs, yet there is a loss of group 1 metabotropic glutamate receptor (mGlu)-stimulated translation. Since several FMRP target mRNAs are known to be localized to dendrites, FMRP is hypothesized to regulate dendritic protein synthesis.
We have previously used biochemical methods applied to synaptoneurosomes to demonstrate a role for FMRP in regulating the translation of PSD-95 mRNA. However, PSD-95 mRNA translation within dendrites has not been directly visualized and the extent of translational dysregulation in Fmr1 KO neurons, and particularly in dendrites, has not been examined.
We performed single-molecule analysis of PSD-95 mRNA translation in dendrites of primary hippocampal neurons using a Venus fluorescent protein-based translation reporter with PSD-95 ORF, 5'UTR and 3'UTR.
We show that PSD-95 mRNA translation is predominantly sporadic and occurs in dendrites and dendritic spines. In WT mouse hippocampal neurons, the rate of PSD-95 mRNA translation in dendrites is rapidly increased following mGlu stimulation with DHPG. By contrast, in Fmr1 KO hippocampal neurons, basal rate of PSD-95 mRNA translation was increased and mGlu-stimulated translation was occluded.
We show that PSD-95 mRNA translation is regulated by elements present in both PSD-95 mRNA 5'UTR and 3'UTR. The data obtained from this cell-based assay corroborate and extend earlier findings obtained with synaptoneurosomes by visualizing dysregulated PSD-95 mRNA translation in dendrites from Fmr1 KO neurons and by identifying the role of 5'UTR in PSD-95 mRNA translation regulation. The observed dysregulation in the dendritic synthesis for PSD-95, a critical regulator of synaptic structure and function, has important implications for understanding how impairments in the synaptic proteome and its dynamic regulation may underlie alterations in dendritic spine morphology and synaptic plasticity in fragile X syndrome.

Title: Altered somatosensory barrel cortex refinement in the developing brain of Mecp2-null mice

Authors: *M. MOROTO[1], A. NISHIMURA[1], M. MORIMOTO[1], K. ISODA[1], T. MORITA[1], M. YOSHIDA[1], S. MORIOKA[1], T. TOZAWA[1], T. HASEGAWA[1], T. CHIYONOBU[1], K. YOSHIMOTO[2], H. HOSOI[1];
[1]Pediatrics, [2]Legal Med., Kyoto Prefectural Univ. of Med., Kyoto, Japan

Abstract: Rett syndrome (RTT) is a neurodevelopmental disorder caused by mutations in the methyl-CpG binding protein 2 (MeCP2) gene. In previous studies, monoaminergic dysfunctions have been detected in patients with RTT and in a murine model of RTT, the Mecp2-null mouse. Therefore, the pathogenesis of RTT is thought to involve impairments in the monoaminergic systems. However, there have been limited data showing that the impairment of monoamines leads to early symptoms during development. We used histochemistry to study the somatosensory barrel cortex in the B6.129P2(C)-Mecp2tm1.1Bird mouse model of RTT. The barrel cortex is widely used for investigating largely serotonin (5-HT) signaling-regulated neuronal development. 5-HT levels were measured by high performance liquid chromatography with electrochemical detection (HPLC/EC), and serotonin transporter (SERT) and 5-HT1B receptor mRNAs were measured in the somatosensory cortex, thalamus and striatum on postnatal days (P) 10, P20 and P40. Mecp2-null mice (Mecp2-/y) had significantly smaller barrel fields than in age-matched wild-type controls (Mecp2+/y) on P10 and P40, but the topographic map was accurately formed. Levels of 5-HT, and SERT and 5-HT1B receptor mRNA expression in the somatosensory cortex did not differ significantly between the Mecp2-null and wild-type mice on P10. However, thalamic 5-HT was reduced in Mecp2-null mice. Our data indicate that a lack of MeCP2 may disturb the refinement of the barrel cortex in the early postnatal period. Our results eliminate a role for somatosensory cortical 5-HT in this mechanism, but suggest that a decrease in thalamic 5-HT might be involved in this phenomenon.

Title: Cortical thickness development associated with fragile X syndrome from childhood to early adulthood

Authors: *E.-M. QUINTIN, J. L. BRUNO, M. M. RAMAN, B. JO, S. HALL, A. LIGHTBODY, A. L. REISS;
Psychiatry, Stanford Univ., Stanford, CA

Abstract: Fragile X syndrome (FXS) is the most common inherited cause of intellectual disability and single gene cause of autism spectrum disorder. FXS is associated with abnormal frontal and temporal brain morphology including the orbitofrontal, medialfrontal, and fusiform gyri (Hoeft et al., 2010) and superior and middle frontal gyri (Bray et al., 2011). Activation of the superior temporal and fusiform gyri during fMRI face and eye-gaze processing tasks is also atypical in FXS (Garrett et al., 2004; Watson et al., 2008). Recently, increased cortical thickness in frontal and temporal areas of individuals with FXS has been associated with lower scores on cognitive measures (Meguid, 2012). We investigated whether cortical thickness of frontal and temporal areas change at different rates for individuals with FXS compared to controls using a longitudinal design.
The study included three groups of female participants: 46 with FXS, 28 with developmental delays of idiopathic origin (DD), and 57 with typical development (TD); and three groups of male participants: 33 with FXS, 31 with DD, and 53 with TD. MRI scans were performed 1 to 3 times for each participant. The total age range including all time points is 10 to 26 years. Images were obtained on a 1.5 Tesla MRI scanner with a spoiled gradient recalled echo sequence. Mean cortical thickness was calculated with Freesurfer 5.0. We performed hierchical linear modeling separately for males and females to estimate cortical thickness trajectories from 10 to 26 years of age and compared the rates of thickness change between groups (FXS vs. TD and FXS vs. DD). Overall, bilateral cortical thinning of most frontal and temporal areas was found for all groups and both sexes. Similar cortical thinning patterns were found for the FXS and TD female groups. Specific group differences include faster rates of cortical thinning for the FXS vs. TD male groups at the left middle frontal and medial inferior frontal gyri (including orbitofrontal cortex); and for the FXS vs. TD female groups at the right fusiform gyrus; and FXS vs. DD female groups at the left medial inferior frontal gyrus. Rates of cortical thinning tended to be slower for

FXS vs. DD male groups at the left and right superior temporal gyrus.
Atypical cortical thinning rates of frontal and temporal areas associated with FXS is consistent with previously reported abnormal brain morphology and activation of those areas. The results of such investigations can potentially provide robust biomarkers to measure the efficacy of specific drug and behavioral interventions since these areas are associated with cognitive and social functioning.

Title: Diurnal increase of apnea and reduced GAD1 mRNA expression in respiratory nuclei in Mecp2-deficient mice

Authors: *M. NISHIYAMA[1], M. ASANO[2], S. IWASA[1], A. SUZUKI[1], T. WADA[1], H. TAKIGUCHI[1], T. SHIRAKAWA[1];
[1]Dept. of Pediatric Dentistry, Nihon Univ. Sch. of Dent., Tokyo, Japan; [2]Dept. of Pathology, Nihon Univ. Sch. of Dent., Tokyo, Japan

Abstract: Rett syndrome (RTT) is caused by mutations in the gene encoding methyl-CpG-binding protein 2 (MeCP2). RTT patients exhibit autistic symptoms, breath holding, seizures and *etc*. It has been shown that breath holding in the patients occurs almost exclusively at daytime. *Mecp2*-null mice (*Mecp2* $^{-/y}$) exhibit frequent apnea similar to that seen in RTT, but there is not a report on its diurnal variation and epigenetic mechanisms underlying the respiratory disturbances are unknown.
We evaluated respiratory functions in unrestrained *Mecp2* $^{-/y}$ using a whole body plethysmography at 2, 3, 5, and 7 weeks of age. At 5 and 7 weeks of age, continuous 24-hour measurement of respiration was carried out in *Mecp2* $^{-/y}$ and wild-type male mice (*wild*). When apnea counts were compared between *Mecp2* $^{-/y}$ and *wild*, it became apparent that the counts were much larger in *Mecp2* $^{-/y}$ than *wild* at all ages examined and throughout the 24h period at 5 and 7 weeks of age. The apnea increased significantly during the light phase of 12:12h light-dark environment in *Mecp2* $^{-/y}$ ($p < 0.01$). In contrast, *wild* showed stable respiratory rhythm and no day-night difference was observed in apnea counts.

Because GABAergic neurotransmission has been reported to be impaired in the brain of *Mecp2* $^{-/y}$, we measured glutamate decarboxylase 1 (GAD1) mRNA expression in the respiratory nuclei (nucleus of the solitary tract and ventrolateral medulla) by quantitative RT-PCR, and found that GAD1 mRNA is reduced in these respiratory nuclei of *Mecp2* $^{-/y}$ compared to *wild* at 2 weeks of age ($p < 0.05$). Methylation analysis of CpG islands in the proximal promoter region of GAD1 DNA extracted from the respiratory nuclei revealed differences of the sites of methylated CpG between *Mecp2* $^{-/y}$ and *wild* while most of the CpGs in the GAD1 promoter were unmethylated. These results indicate that the altered GAD1 expression in the respiratory nuclei may be responsible for the appearance of apnea in *Mecp2* $^{-/y}$.

Title: Rett Syndrome-related genes share common pathogenic pathways

Authors: N. MORELLO[1], R. PIZZO[1], E. CALCAGNO[1], E. AMENDOLA[2], C. GROSS[2], M. SASSOÈ-POGNETTO[1], *M. GIUSTETTO[1];
[1]Dept. of Neurosci., Univ. of Torino, Torino, Italy; [2]European Mol. Biol. Lab. (EMBL), Monterotondo (Rome), Italy

Abstract: Rett syndrome (RTT) is an X-linked progressive neurodevelopmental disorder. RTT is typically characterized by a broad range of deficits including loss of language skills and hand use, cognitive and motor alterations. While most RTT patients show mutations of the X-linked methyl-CpG-binding protein 2 (MECP2) gene, recently a rare RTT-like syndrome was shown to be associated with mutations in the X-linked cyclin-dependent kinase-like 5 (CDKL5) gene that is characterized by early onset seizures. Even though patients carrying MECP2 or CDKL5 mutations show peculiar behavioural and cognitive alterations, they share overlapping features including stereotypical hand movements and deficient language acquisition. Recent evidences suggest that RTT neurological symptoms may arise from excitation/inhibition balance

abnormalities in specific neocortical regions which likely stem from dysfunctional interneurons. However, the cellular and molecular determinants of such dysfunctions are largely unknown. In this study, we analyzed several components of the GABAergic system in two murine models of RTT, the Mecp2tm1.1Jae mutants and a newly-generated Cdkl5-KO strain. Using immunofluorescence, we studied whether the lack of MeCP2 or CDLK5 may alter the normal organization of three different populations of GABAergic neurons and the architecture of inhibitory synapses in neocortical circuits. We found that Mecp2 deletion causes an increase of the density of both parvalbumin (PV) and calretinin (CR) interneurons even at early asymptomatic postnatal stages, without affecting somatostatin (SST) interneurons. A similar increase of PV cell density was also present in Cdkl5-KO mice. The CR-positive interneurons showed an abnormal morphology both in Mecp2 and Cdkl5 mutants. Quantitation of immunolabeling showed a significant increase of perisomatic neuroligin-2 NL2-positive synaptic puncta in MeCP2-KO cortices while, surprisingly, no differences were found in the number of VGAT-positive puncta. These results indicate that the expression of this GABAergic postsynaptic adhesion molecule is modulated by MeCP2. To test whether these alterations in the organization of GABAergic connectivity were cell autonomous, we used a Dlx5/6-Cre line to remove MeCP2 from a subset of forebrain GABAergic neurons. These analyses revealed similar phenotypes in conditional mutants and MeCP2 null mice. Our data support the idea that mutations of RTT-related genes share common pathogenic pathways, namely the abnormal organization of GABAergic systems, that may produce excitation/inhibition imbalance in the brain.

Title: Development of cortical activity in a rat model of Fragile X Syndrome *In vivo*

Authors: *J. BERZHANSKAYA[1], A. S. GORIN[2], M. A. PHILLIPS[1], M. T. COLONNESE[1]; [1]Pharmacol. & Physiol., [2]Engin. and Applied Sci., George Washington Univ., Washington, DC

Abstract: A critical question in the etiology of developmental neurological disorders is the extent to which pre-symptomatic circuit perturbations contribute to disease phenotype. Taking advantage of a newly developed model for FXS in the rat (the Fragile X mental retardation protein 1 mutant (Fmr1KO)), a species for which visual cortical activity development has been carefully matched to human neonates, we are examining the developmental trajectory of spontaneous and visually evoked activity in the unanesthetized visual cortex of Fmr1KO and wild-type Sprague-Dawley rats between birth and adulthood. In control animals, developing visual cortex passes through two clear functional modes with the transition two days before eye-opening (two weeks before term in humans). During the first period, spontaneous retinal waves (or visual stimuli) drive rapid oscillations on a background of network silence. During the second period, cortical active states emerge, leading to continuous background activity and mature-like visual evoked potentials. The cortical activity patterns of Fmr1KO rats were qualitatively similar to wild-type controls during both developmental periods. During the early developmental period, KO rats demonstrated rapid oscillations on a background of network silence. Transition to the late period occurred before eye opening, as in controls, suggesting no appreciable developmental delay. Quantitative analysis of local field potentials (LFP) during wakefulness showed signs of hyper-excitability at P19-20, with an increase in gamma-band power relative to controls. Continuing analysis of spontaneous and visually evoked LFP and spiking activity throughout the depth of cortex will be used to further characterize the developmental trajectory of cortical excitability in Fmr1KO animals.

Title: Selective disruption of mGluR5-Homer interactions mimics multiple phenotypes of Fragile X Syndrome in mice

Authors: *K. A. COLLINS[1], W. GUO[1], S. A. HAYS[1], G. MOLINERO[2], R. PAYLOR[3], P. F. WORLEY[4], K. M. HUBER[1];

[1]Neurosci., UT Southwestern Med. Ctr. At Dallas, Dallas, TX; [2]Neuropharm., INM Neuromed, Pozzilli, Italy; [3]Dept. of Neurosci., Baylor Col. of Med., Houston, TX; [4]Dept. of Neurosci., John Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Fragile X Syndrome (FXS) results from transcriptional silencing of the Fmr1 gene and is the most common inherited form of intellectual disability and a leading genetic cause of autism. Altered function of the Gq-coupled, Group 1 metabotropic glutamate receptors, specifically mGluR5, occurs in the FXS mouse model, the Fmr1 knockout (KO) mouse. Pharmacological and genetic reduction of mGluR5 reverses many phenotypes of FXS in animal models and mGluR5 antagonists are currently in clinical trials in FXS and autism patients. A mechanism for mGluR5 dysfunction in Fmr1 KO mice is suggested by the findings that mGluR5 is less associated with its scaffolding protein Homer and restoration of mGluR5-Homer interactions rescues many phenotypes of Fmr1 KO mice (Giuffrida et al., J. Neurosci. 2005; Ronesi et al., Nat. Neurosci. 2012). The Homer family of proteins binds to the intracellular C-terminal tail of mGluR5 and forms multi-protein signaling complexes at the postsynaptic density with mGluR5 and its downstream effectors. Disruption of mGluR5-Homer scaffolds leads to abnormal mGluR5 localization, signaling as well as constitutive or overactive mGluR5. We hypothesized that selective disruption of mGluR5 from Homer may be sufficient to mimic many phenotypes of Fmr1 KO mice. To test this hypothesis, we examined mice with a knockin mutation of mGluR5 (F1128R; mGluR5FR; Cozzoli et al., J. Neurosci. 2009) that abrogates binding to Homer to determine if these mice mimic phenotypes of Fmr1 KO mice. Many phenotypes of Fmr1 KO mice are mimicked in the mGluR5FR mice including mGluR5 localization at the synapse, mGluR5-signaling to translation, neocortical hyperexcitability, and open field behavior. Synaptic plasticity and other behavioral phenotypes are currently being examined. These results indicate that disruption of mGluR5-Homer scaffolds is sufficient to mimic multiple phenotypes of Fragile X Syndrome and reveals specific molecular mechanisms of a complex brain disease.

Title: Cellular mechanisms of dopaminergic dysfunction in Angelman syndrome model mice

Authors: *J. BERRIOS[1], B. D. PHILPOT[2];
[1]Neurosci., [2]Cell Biol. and Physiol., Univ. of North Carolina At Chapel Hill, Chapel Hill, NC

Abstract: Increased *UBE3A* dosage has been linked to autism spectrum disorders, while maternal mutations or deletions in *UBE3A* cause Angelman syndrome (AS). AS is a debilitating neurodevelopmental disorder characterized by intellectual disability, ataxia, epilepsy, abnormal sleeping patterns, developmental delay, and a happy disposition. Previous studies suggest that aberrant dopamine transmission may contribute to AS behavioral phenotypes. Consistent with this idea, recent studies in AS model mice indicate that maternal *Ube3a* loss is associated with pathway-specific deficits in dopamine release (Riday et al., 2012). Specifically, AS mice have increased dopamine release in the mesolimbic pathway, but decreased dopamine release in the nigrostriatal pathway. These data indicate that UBE3A protein is a major regulator of proper dopamine signaling. Based on these results, we hypothesize that these opposing, pathway-specific effects are due to cell type-specific synaptic deficits from projection dopaminergic neurons in the Ventral Tegmental Area (VTA) and Substantia Nigra pars Compacta (SNc). Using *in vitro* slice electrophysiology, our preliminary data indicate that changes in dopamine release are linked to differences in intrinsic neuronal excitability within the midbrain in AS model mice. Using this approach we are investigating the mechanism by which UBE3A regulates dopaminergic transmission in AS model mice, with the expectation that this knowledge will guide more rational treatments for dopaminergic dysfunction in individuals with AS.

Abstract: Rett Syndrome is a debilitating childhood-onset neurodevelopmental disorder that is predominantly caused by mutations in methyl-CpG-binding protein 2 (MEPC2). Using the MeCP2 knockout (KO) mouse model of the disease we uncovered a novel miRNA-mediated molecular pathway that bridges the observed alterations in Brain-derived neurotrophic factor (BDNF) and Insulin-like growth factor 1 (IGF1) expression in the brain of MeCP2 KO mice. Importantly, chronic treatment with a β-2 adrenergic receptor agonist completely normalized the expression of the components of the affected molecular pathway in the cerebellum of Mecp2 KO mice, and resulted in greatly increased survival, improved respiratory function, social recognition, and motor coordination; all cardinal symptoms of Rett syndrome. Notably, co-administration of the same β-2 adrenergic receptor agonist with recombinant human IGF1, further ameliorated the phenotype of MeCP2 KO mice, and resulted in a notable increase in survival. In parallel we used patient-derived induced pluripotent stem cells (IPSCs) to screen more effectively for miRNAs that are affected in Rett Syndrome. Our results from IPSC-derived neuronal cultures revealed among others an additional miRNA family that is robustly increased in two different patient-derived samples, at two different developmental stages, and following viral-mediated knockdown of WT samples. Protein and RNA expression analysis uncovered altered levels of known targets of the affected miRNA family, which are upstream regulators of BDNF expression. In summary we show using both a mouse and IPSC-model of Rett syndrome that a subset of Mecp2-regulated miRNAs are important effectors of complex regulatory networks related to brain growth factor expression, and reveal novel therapeutic alternatives for the treatment of Rett syndrome.

Title: Molecular regulation of neuronal size in MeCP2 A140V mutant mice

Authors: *S. RANGASAMY, S. OLFERS, V. NARAYANAN;
Developmental Neurogenetics, Barrow Neurolog. Inst., PHOENIX, AZ

Abstract: Rett syndrome (RTT), an X-linked dominant neurological disorder caused by mutation of the MeCP2 gene, is characterized by stereotypical hand movements and autistic features. Pathological studies in mouse models and human cases of Rett syndrome have shown a reduction in neuronal size, dendritic complexity and increased cell packing density. Our laboratory has created a mouse model (MeCP2 A140V "knock-in" mutant) expressing a human MeCP2 mutation linked to an X-linked mental retardation phenotype. In this model, we have identified decreased dendritic branching of cortical layer III pyramidal neurons, and increased cell packing density in several brain regions. Here, we report measurements of neuronal soma and nuclear size in cultured neurons from A140V and wild type (WT) mice. Soma size, measured after staining with beta III tubulin, was reduced by ~30% reduction at 21 days of in vitro (DIV) in mutant hippocampal neurons compared to WT. This reduction in neuronal soma size is observable as early as 3 DIV and is accompanied by reduction in nuclear size. The mammalian target of rapamycin (mTOR) signaling network, consisting of two catalytic subunit complexes mTORC1 and mTORC2, is crucial for neuronal development and long-term modification of synaptic strength. Recent studies have shown that mTORC2 plays an important role in regulation of brain morphology, neuronal size and function. Loss of Rictor protein, a component of mTORC2 pathway, results in a smaller neuronal phenotype. In this study, we explored mTOR pathway molecules in MeCP2 A140V mutant mice and found a significant decrease in the levels of Rictor protein in brain homogenates of male MeCP2 A140V animals. We also compared gene expression profiles (male A140V to WT) in layer 4/5 cortical pyramidal neurons of 2-week old male mice using mouse whole genome expression arrays. Array analysis indicated that there is an alteration of IGF-1 pathway genes which are implicated in the pathogenesis of Rett syndrome. These results demonstrate that the major cell size regulator pathways involving IGF-1 and mTORC2 are significantly down regulated in MeCP2 A140V mice. Together, these findings suggest that MeCP2 A140V mutation modulate mTORC2 and IGF-1 pathways resulting in smaller neurons, which may contribute to neurologic manifestations seen in Rett syndrome.

Title: Functional analysis of MeCP2, the Rett syndrome responsible factor, in neural stem cells

Authors: *H. NAKASHIMA, K. TSUJIMURA, I. KOICHIRO, K. NAKASHIMA;
Dept. of Stem Cell Biol. and Med., Grad. Sch. of Med. Science, Kyushu Univ., Hukuoka/Hukuoka, Japan

Abstract: Rett syndrome (RTT) is a severe neurodevelopmental disorder affecting almost exclusively females. RTT is caused by sporadic mutations in the X-linked transcriptional regulator methyl-CpG binding protein 2 (*MECP2*) gene. Previous study has shown that MeCP2 is involved in neuronal maturation rather than fate specification of neural stem cells (NSCs). However, a recent study indicated that astrocytic differentiation of MeCP2 deficient mouse ES cell-derived NSCs was dramatically accelerated. In addition, we have previously shown that overexpression of MeCP2 in mouse NSCs promoted neuronal differentiation while it inhibited astrocytic differentiation. Thus, the functional roles of MeCP2 in NSCs remain ambiguous. Using both gain-of-function and loss-of-function approaches, we here examined whether MeCP2 is indeed implicated in the process of NSCs fate determination. We first found that MeCP2-overexperssion and -knockdown had no significant effect on either proliferation or cell death of NSCs. Second, we observed that the reduction of MeCP2 expression with shRNA promoted astrocytic differentiation at the expense of neuronal differentiation of NSCs. Consistent with the results of the knockdown experiments as above, enhanced astrocytic differentiation of NSCs derived from MeCP2 knockout (KO) fetal brain was detected. We confirmed that protein levels of astrocyte specific markers such as glial fibrillary acidic protein (GFAP) and aldehyde dehydrogenase 1 family, member L1 were increased in MeCP2-KO cortex and spinal cord compare to those in wild-type. Intriguingly, it has also been reported that protein levels of GFAP is upregulated in RTT patients.
Taken together, our findings suggest that MeCP2 plays important roles in fate determination of NSCs *in vitro* and *in vivo*.

Title: Stimulus reconstruction using EEG reveals impaired low frequency speech envelope encoding (< 8Hz) in developmental dyslexia

Authors: *A. J. POWER, U. GOSWAMI;
Dept of Psychology, Ctr. For Neurosci. In Educ., Cambridge, United Kingdom

Abstract: Developmental dyslexia is a specific difficulty in acquiring reading found across languages and orthographies. Cognitively dyslexia is characterised by difficulties in identifying and manipulating speech sounds - a 'phonological deficit'. Auditory cortical oscillations have been proposed to play an important role in phonological encoding and speech perception. Phonological encoding is thought to involve temporal 'sampling' of information from the speech stream at different rates, phase-resetting ongoing oscillations so that they are aligned with similar envelope modulation rates in the input. Information from these modulation rates is then bound together for speech perception. Slow auditory cortical oscillations (< 8Hz) entrain to the low frequency envelope information in speech, important for syllabic parsing and encoding prosodic structure. It has been hypothesised that the encoding of the slower frequency information is impaired in developmental dyslexia, leading to the observed phonological deficit (Goswami, 2011). An increasingly popular method for assessing the extent of encoding of auditory stimuli is stimulus reconstruction (Mesgarani et al., 2009). This method determines what acoustic information can be reconstructed from recorded neural activity. Comparing this neural reconstruction to the actual stimulus gives a measure of encoding accuracy. Here we employ this method to assess low frequency speech envelope encoding in children with developmental dyslexia (DY) as well as typically developing age matched control subjects (CA) and reading age matched (younger) controls (RA). Participants were presented with 8-channel noise vocoded speech stimuli. The sentences were four words long. Subjects were asked to repeat the sentences aloud and were scored on accuracy of word report. The stimuli were semantically unpredictable but grammatically correct sentences (e.g. Arcs blew their cough). This was done to eliminate potential compensatory contextual cues within the sentences. We found that DYs and RAs performed significantly worse than CAs in the word report task. EEG was also recorded while performing the task and the stimulus reconstruction procedure was applied to the data. We found the quality of low frequency envelope encoding to be significantly worse in DYs than CAs. RAs did not differ from either group. Furthermore, the quality of low frequency envelope encoding was significantly related to behavioural measures of phonological awareness as well as to performance on the word report task. These results provide support for the temporal sampling framework theory of developmental dyslexia (Goswami, 2011).

Title: Development of white matter in children with developmental dyslexia

Authors: *I. KRAFT, M. A. SKEIDE, J. BRAUER, A. ANWANDER, A. D. FRIEDERICI; Neuropsychology, Max Planck Inst. For Human Cognitive and Brain Sci., Leipzig, Germany

Abstract: During their first years at school children learn how to read and to write. These two skills are crucial not only for educational success but also for an active participation in social life. However, one out of five school children suffer from dyslexia, a development disorder which is characterized by impairments in the domain of reading and writing, despite age-typical development of other cognitive abilities. A deficit in phonological awareness is discussed as one of the impairments underlying dyslexia.

The goal of our study was to investigate the relation between white matter integrity and phonological awareness as well as reading skills in 10-year old German children. We acquired diffusion tensor imaging (DTI) data from 41 children (24 males, 17 females) in order to measure individual fractional anisotropy (FA) values within the entire white matter skeleton. In addition, we used standardized psychometric tests to assess the basic reading skills and the phonological awareness of each participant.

A regression analysis revealed that the both test scores are significantly associated with FA values of the inferior longitudinal fasciculus (ILF), which is in line with previous findings from English suggesting an involvement of the ILF in reading (Rimrodt et al., 2010; Yeatman et al., 2012). Moreover, the psychometric measures are significantly related to FA values in the anterior corona radiate (ACR) suggesting an involvement of the ACR in phonological manipulation as it has been associated with working memory tasks (Nagy et al., 2004; Niogi & McCandliss, 2006; Olesen et al., 2003).

Taken together, our results confirm that white matter fractional anisotropy can serve as a neurobiological marker for a developmental dyslexia also for German, and thus possibly across languages. In particular our results suggest that the ACR is not only involved in pure working memory tasks, but also in basic phonological processing, which is an important prerequisite for reading and writing. In the future, further longitudinal studies are needed to investigate the interplay of altered fiber maturation and impaired phonological awareness as well as reading skills during childhood.

Title: Language deficits in autism and assessment of the Cntnap2 mouse

Authors: *A. RENDALL, D. T. TRUONG, B. C. CASTELLUCCIO, I. M. EIGSTI, R. H. FITCH;
Psychology, Univ. of Connecticut, Storrs, CT

Abstract: Autism Spectrum Disorder (ASD) is a heterogeneous neurodevelopmental disorder with core symptoms that include atypical social interactions, language impairments, and repetitive behaviors. This developmental disorder has a strong yet complicated genetic basis, with at least 100 risk genes identified so far. One of these genes, contactin associated like protein 2 (*CNTNAP2*), was first associated with Specific Language Impairment and more recently has been linked to ASD. *CNTNAP2* is located on chromosome 7 and is downregulated by forkhead box protein 2 (*FOXP2*), a gene involved with speech and language. *CNTNAP2* is responsible for encoding a cell adhesion protein that regulates signal transmission at the synapse. In addition, *Cntnap2* has been found to promote myelin formation and speed/efficacy of signal transmission. Therefore, disruption of *CNTNAP2* may impair synapse formation, resulting in disruptions in language development - - a core feature of ASD. Clinically relevant research with language impaired groups including ASD populations has found that low-level deficits in temporal auditory processing may impair language development. In contrast, hyper-acute (e.g., improved) pitch of human speech may correlate with early language delays in ASD. To better understand the behavioral and biological underlying mechanisms of ASD, a transgenic mouse model was generated with a genetic knockout (KO) of the rodent homolog of *CNTNAP2* (*Cntnap2*). Previous studies of this model investigated by Peñagarikano et al. in 2011 reported poor social interactions, behavioral perseveration, and reduced vocalizations. The current study was designed to further assess the intermediate behavioral phenotype of this mouse model, focusing on auditory processing phenotype in this mouse model, including rapid temporal auditory processing and pitch discrimination abilities. Results show that *Cntnap2* KO mice exhibit significant deficits in rapid auditory processing as well as significant strengths in pitch discrimination. These findings suggest that *CNTNAP2* may have an underlying role in the development of neural systems important to auditory temporal processing, and disruption of this function could be associated with language impairments in ASD.

Title: Auditory processing and memory impairment in mice with a genetic knockout of Dcdc2, the rodent homolog of a candidate dyslexia risk gene

Authors: *D. T. TRUONG[1], A. CHE[2], A. R. RENDALL[1], C. E. SZALKOWSKI[3], J. J. LOTURCO[2], R. H. FITCH[1];
[1]Behavioral Neurosci., [2]Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT; [3]Dept. of Biotechnical and Clin. Lab. Sci., Univ. of Buffalo Sch. of Med., Buffalo, NY

Abstract: Developmental dyslexia is one of the most commonly diagnosed neurobehavioral disorders in school aged children and is characterized by a chronic impairment of reading ability. Gene variants in the region of DCDC2, a neurally expressed candidate dyslexia risk gene, have consistently been associated with reading disability in several independent samples. Moreover, DCDC2 variants have been associated with impairments in phonological processing and working memory ability within Dyslexic populations. To better examine the behavioral and biological underpinnings of DCDC2, transgenic mouse models have been developed, and initial behavioral characterization of mice with a genetic knockout (KO) of the rodent homolog of DCDC2 (Dcdc2) has found evidence of visuo-spatial learning impairments on the Hebb Williams Maze. To our knowledge, auditory processing ability (a component of phonological processing in humans) has not yet been assessed in Dcdc2 KO mice. The current study was designed to further expand upon clinical as well as previous behavioral findings in rodents by examining auditory processing ability and both working and reference memory ability in Dcdc2 KO mice. Auditory processing ability was measured using an embedded tone task -- a paradigm previously adapted in neuroanatomical rodent models of dyslexia. Both working and reference memory ability was examined concurrently using a water version of the 4/8 spatial radial arm maze. Results from this study not only reveal an auditory processing impairment in Dcdc2 KO mice, but also a profound memory impairment in Dcdc2 KO mice in comparison to wildtype controls across both working and reference memory domains. Further analysis of strategy to solve the water maze revealed

that both Dcdc2 and wildtype controls utilized comparable spatial strategies to navigate the maze, suggesting that increased errors made by Dcdc2 KO mice were a result of a spatial memory impairment and not due to the utilization of kinesthetic (chaining) strategies to solve the maze. Overall, these data support clinical findings, and also expand upon rodent work suggesting that disruption of DCDC2 is associated with phonological and memory impairment. Furthermore, since both phonological and working memory deficits comprise a prominent component of dyslexia, the current results provide insight to the underlying behavioral etiology of reading dysfunction that may be mediated by alteration in DCDC2 function.

Title: Speech sound processing deficits and training-induced neural plasticity in rats with dyslexia gene knockdown

Authors: *T. M. CENTANNI[1], A. B. BOOKER[2], F. CHEN[2], C. T. ENGINEER[1], A. M. SLOAN[1], K. TRULL[2], N. WASKO[2], R. L. RENNAKER[1], J. J. LOTURCO[2], M. P. KILGARD[1]; [1]Univ. of Texas At Dallas, Richardson, TX; [2]The Univ. of Connecticut, Storrs, CT

Abstract: Reduced expression of the dyslexia associated gene Kiaa0319 in rats (KIA-) causes degraded responses to phoneme stimuli as well as increased trial-by-trial variability in onset latency. We have previously shown that in utero RNAi of this gene causes increased trial-by-trial variability in auditory cortex responses to tone and speech sound stimuli. Here we report that in utero RNAi of this gene causes significant behavioral speech sound processing impairments in rats. KIA- rats needed twice as much practice on a speech discrimination task to perform at control levels. The percentage of neurons affected by RNAi is strongly correlated with speech discrimination ability. KIA- rats are able to learn difficult speech discrimination tasks, but require long training periods and benefit from focused training using truncated speech sounds. Extensive behavioral training (>10 weeks) was able to restore trial by trial neural firing variability. This amount of training also restored (to control levels) the ability of primary and posterior auditory cortices to accurately encode speech sound stimuli. These results provide the first direct evidence that in utero suppression of the dyslexia associated gene KIAA0319 can

cause behavioral phoneme processing impairments and extensive training can ameliorate both behavioral and neural firing deficits.

Abstract: Writing requires knowledge of a phonological system, an ability to transform phonemes into graphemes, specific movements to draw letters properly and an efficient use of space to distribute, separate and join syllables. These aspects of writing are perturbed in children with visospatial dysgraphia. The symptoms include omissions and additions of letters, inability to separate words and difficulties to maintain horizontality while writing without lines. A very common error due to dysgraphia is the distortion and rotation of letters with similar form, for example, children with dysgraphia misperceive the pairs (b,d), (p,q) and (6,9). Moreover, children with this condition also present problems in calculating, reading, building or solving puzzles. Since this whole situation increases the risk of failure and school desertion, it is necessary to generate new methods to avoid children failure using highly stimulating tools in order to motivate them to succeed. That is why our project consisted of the following: we developed a computer program (videogame inspired) that children can use with a graphic pen-tablet. Children are required to write specific letters that the program, consisting of a simple pattern recognition system, identify so that it can give users a positive or negative feedback depending on their performance and using a goal-directed approach. Our preliminary results, from twenty regular students, support previous findings showing that children are highly

motivated to work with our system. Results from 15 dysgraphic children are currently being analyzed. Financial support from UPAEP 30108-1030

Title: Induced neocortical neuronal migration disorder affects cell number in the ventral cochlear nucleus

Authors: G. C. JOHNSON, W. T. ADLER, M. P. PLATT, K. A. WRIGHT, *G. D. ROSEN, A. M. GALABURDA;
Neurol., Beth Israel Deaconess Med. Ctr., BOSTON, MA

Abstract: Previous research demonstrated that individuals with developmental dyslexia have neocortical neuronal migration disorders, including microgyria. Further, developmental dyslexics also have difficulties in rapid processing of visual and auditory information. In rats, neonatal freeze injury to the cortical plate results in malformations resembling focal microgyria. In males, induced microgyria leads to changes in cell size distribution in the medial geniculate nucleus and defects in processing rapid auditory stimuli. In contrast, female littermates with identical malformations have no behavioral or anatomic consequences. In this experiment, we tested whether induced neocortical malformations in male and female rats disrupt the cellular architecture of a brainstem auditory nucleus, the ventral cochlear nucleus (VCN).
We examined male and female rats with unilateral or bilateral microgyria induced in either the parietal or temporal cortices against sham surgery. We estimated the numbers and sizes of neurons in the VCN using optical fractionator and nucleator probes, respectively. We found fewer neurons in the VCN of males and females, combined, following temporal vs. parietal microgyria. In males, there were significantly fewer cells in the VCN in both parietal and temporal microgyria groups when compared to sham littermates. By contrast, there were no significant differences among the groups in females. Further, the decrease in neuronal number among males was more pronounced in the VCN contralateral to the microgyria than the ipsilateral VCN. There were no differences in cell sizes between microgyric rats and controls for

either sex or both sexes combined. This is the first demonstration of histometric changes at the level of the brainstem associated with focal neuronal migration disorders indicating far-reaching plasticity effects. We argue that the brainstem changes could be directly responsible for the low level auditory processing defects exhibited by rats with this injury.

Title: Physiological but not anatomical abnormalities in the auditory thalamus of ectopic BXSB/MpJ-Yaa mice

Authors: *J. MATTLEY[1], L. A. ANDERSON[1], J. F. LINDEN[1,2];
[1]UCL Ear Inst., London, United Kingdom; [2]Dept. Neuroscience, Physiol. & Pharmacol., UCL, London, United Kingdom

Abstract: In the BXSB/MpJ-Yaa inbred mouse strain, approximately half the animals spontaneously develop nests of displaced neurons in cortical layer I, called ectopias. Neocortical ectopias have also been reported to occur in humans with developmental disorders such as dyslexia. Interestingly, although the ectopias occur outside the auditory cortex, both human studies of spontaneously occurring ectopias and studies of rats with induced cortical malformations have observed an association with anatomical abnormalities within the auditory thalamus. Previously, we have shown that ectopic BXSB/MpJ-Yaa mice have a physiological deficit in auditory thalamic processing, despite apparently normal hearing sensitivity. The aim of this current study was to determine whether the animals also have anatomical abnormalities in the auditory thalamus.
Following in vivo electrophysiological recordings, brain tissue was processed for histology. Alternate coronal brain sections were stained for cytochrome oxidase to differentiate thalamic

subdivisions, and Nissl substance to reveal cortical ectopias and thalamic cell density. Volumes of cortical ectopias and auditory thalamic subdivisions were calculated using area estimates obtained by drawing borders on images of stained sections. Cell packing densities were estimated with a pixel-based density index, calculated from the distributions of pixel intensities across different image sections for the same subdivision and animal. All ectopic animals had at least one ectopia located in the motor cortex. Anatomical analysis showed no significant differences in thalamic volume or cell packing density between ectopic and non-ectopic mice, for either the whole auditory thalamus or any individual subdivision, even though positive controls for detection of differences between subdivisions were highly significant. These results suggest that previously observed physiological deficits in the auditory thalamus of ectopic BXSB/MpJ-Yaa mice might arise outside the auditory thalamus, or from causes with no anatomical correlate.

Title: Differential contributions of Foxp2 to motor-skill learning

Authors: *C. A. FRENCH[1], C. FELICIANO[1], M. CORREIA[1], V. B. PAIXÃO[1], X. JIN[2], S. E. FISHER[3], R. M. COSTA[1];
[1]Champalimaud Ctr. For the Unknown, Lisbon, Portugal; [2]The Salk Inst. for Biol. Studies, La Jolla, CA; [3]Max Planck Inst. for Psycholinguistics, Nijmegen, Netherlands

Abstract: Disruptions of the *FOXP2* gene cause a severe developmental speech and language disorder. This has been well studied in the KE family where a heterozygous *FOXP2* mutation is dominantly inherited. Affected individuals have difficulty producing the sequences of orofacial motor movements necessary for fluent speech. This feature has been proposed to be central to the disorder, although other expressive and receptive language problems also exist. *FOXP2* encodes a transcription factor that is expressed in the cortico-striatal and cortico-cerebellar circuits required for sensorimotor integration and motor-skill learning, and imaging studies of the KE family have shown structural abnormalities in the caudate nucleus and ventral cerebellum. The FOXP2 protein is also highly conserved in other vertebrate species, with only 3 amino acid changes between humans and mice. Mice carrying the KE-family mutation (*Foxp2-R552H/+*)

have motor-skill learning deficits and lack striatal long-term depression. We also showed that they have altered *in vivo* striatal activity during the learning of a motor task. We are now deleting Foxp2 from A. selected brain regions (cortex, striatum or cerebellar Purkinje cells) and B. a defined time point (adulthood). This genetic approach is being combined with an operant motor-sequence learning task which allows us to examine the microstructure of animals' behaviour. In the first phase of training, mice must complete a sequence of 8 lever presses to obtain a food reward. After 12 days a time constraint is added and the sequence must be performed at increasingly high speeds. Surprisingly, initial data showed that the press rate of *Foxp2-R552H/+* and heterozygous knockout mice was faster than that of controls, in contrast to cerebellar mutants which had a slower press rate. A decreased press rate was also evident in striatal mutants during the high-speed phase of the task. Histograms of inter-press-intervals revealed more subtle changes and distribution differences were evident in all mutant lines relative to controls. Lever presses were also divided into bouts (sequences of presses) which evolved during training. *Foxp2-R552H/+* and heterozygous knockouts produced sequences of a shorter duration with reduced inter-sequence intervals, whereas cerebellar mutants produced sequences of a longer duration with increased inter-sequence intervals. These data suggest that Foxp2 function in distinct subcircuits may differentially affect motor-skill learning.

Abstract: OBJECTIVE: Neurofibromatosis 1 (NF1) is caused by a mutation in the neurofibromin gene, and represents one of the most common single gene causes of learning disabilities. NF1 is characterized by impairments in frontally-mediated cognitive functions, such as attention, working memory, and inhibition, as well as significant social dysfunction. However, little is known about the functional connectivity (FC) of the resting brain in NF1.
METHOD: Two separate seed-based-analyses of resting-state functional MRI data were used to investigate FC associated with the posterior cingulate cortex (PCC) and with the ventromedial prefrontal cortex (vmPFC), known hubs of the Default Mode Network (DMN), in 12 youth with NF1 and 15 typically developing controls. The groups did not differ in terms of age, gender and translational or rotational motion during the scan.
RESULTS: FC maps derived from the PCC seed region recapitulated the classic DMN in both healthy controls and individuals with NF1, with significant connectivity between the PCC, lateral parietal cortices and the vmPFC apparent in both groups. However, relative to controls, NF1 participants showed significantly weaker FC between the PCC and other DMN nodes, including the vmPFC and left frontal pole. FC maps derived from the vmPFC seed region also revealed significant within-network connectivity between the vmPFC, lateral parietal cortices and the PCC in both groups. However, relative to controls NF1 participants showed significantly reduced FC between the vmPFC and the PCC.
CONCLUSIONS: We observed reduced strength and extent of DMN activity in subjects with NF1, with typically developing controls showing more robust long range connectivity between the two main hub regions of the DMN. Given that the DMN is active both in passive resting states and in social information-processing, these findings suggest a possible neurobiological substrate for social deficits in NF1.

Title: Speech-related brain activity in stuttering and cluttering: Common dysfunction in the motor network

Authors: *E. L. CONNALLY[1], D. WARD[2], C. PLIATSIKAS[3], K. E. WATKINS[1];
[1]Exptl. Psychology & Oxford Ctr. for Functional MRI of the Brain (FMRIB), Univ. of Oxford, Oxford, United Kingdom; [2]Clin. Language Sci., [3]Ctr. for Integrative Neurosci. and Neurodynamics, Univ. of Reading, Reading, United Kingdom

Abstract: Stuttering and cluttering are disorders affecting the flow of speech. People who stutter (PWS) typically know what they want to say but produce speech characterized by repetitions and prolongations of speech sounds and silences. The speech of people who clutter (PWC) is disorganized or rapid, and thought to reflect a problem in both planning and execution of speech. PWS show structural and functional abnormalities in the speech and motor system relative to controls (CON). The neural correlates of cluttering are unknown, however. Here, we explored brain activity during overt picture description and sentence reading using sparse-sampling functional MRI (3T, 32 axial slices 4 mm ^{3}, TR=9s (7s delay), TE=30ms) in 17 PWS (aged 19 - 54 yrs, 4 females), 17 PWC (aged 20 -55 yrs, 4 females), and 17 CON (aged 19 - 53 yrs, 4 females). Activity in each condition relative to a silent baseline in PWS and PWC was compared to CON and thresholded at z>2.3, $p < .01$ (uncorrected). In general, overt speech production evoked overactivity in PWC relative to CON and underactvity in PWS. Specifically, in both speaking conditions, PWC had greater activity than CON in ventral premotor cortex bilaterally, pre-supplementary motor area and right superior temporal suclus, whereas PWS had less activity than CON in right pars opercularis, parietal operculum and angular gyrus. In addition, during picture description only and in comparison with CON, PWC showed greater activity in right ventral striatum, whereas PWS had greater activity in ventral premotor cortex bilaterally and pre-supplementary area; both PWC and PWS showed less activity in lateral cerebellum bilaterally. During reading only, PWC had less activity relative to CON in left pars orbitalis and hippocampus while PWS showed less activity in the middle frontal gyrus, angular gyrus and caudate nucleus bilaterally and the left pars opercularis and pars orbitalis. In summary, PWC and PWS showed the same pattern of abnormally high activity in the ventral premotor cortex bilaterally and pre-supplementary motor area accompanied by reduced activity in the lateral cerebellum during picture description. Notable differences between the groups were also seen; the dorsal striatum was underactive in PWS whereas in PWC the ventral striatum was overactive. Our results support the idea that these two fluency disorders share a common underlying pathology but that differences between them exist and reflect group differences in the specific deficits in execution and planning of speech that characterise these two disorders.

Title: GABAergic neuron-specific gene expression profiling in models of Rett Syndrome

Authors: *H.-T. CHAO[1,2], P. YU[2], M. HEIMAN[3], S. GONG[4], N. HEINTZ[4], J. L. NEUL[2], C. ROSENMUND[5], H. Y. ZOGHBI[2], C. A. SHAW[2];
[1]Pediatric Neurol., Texas Childrens Hosp., Houston, TX; [2]Baylor Col. of Med., Houston, TX; [3]MIT, Boston, MA; [4]The Rockefeller Univ., New York City, NY; [5]Charite Universitaetsmedizin, Berlin, Germany

Abstract: Rett syndrome (RTT) is caused by mutations in *MECP2* the gene encoding methyl-CpG-binding protein 2 (MeCP2), a protein implicated in chromatin remodeling. RTT is characterized by neurological regression, impaired cognitive and motor function, repetitive stereotypies, and altered social behavior. We found that cell type specific MeCP2 deficiency in GABAergic neurons recapitulates nearly all features of RTT, suggesting that MeCP2 is a critical factor in the regulation of GABAergic function and that dysfunction of GABAergic signaling is critical in RTT pathogenesis. Previous gene expression studies revealed large numbers of transcriptional changes associated with constitutive MeCP2 deficiency, however it remains unclear how these changes are related to loss of MeCP2.
To elucidate the extent to which transcriptional changes are due primarily to loss of MeCP2 or are secondary to the cellular context of MeCP2 deficiency, we utilized models of constitutive MeCP2 deficiency (*Mecp2*$^{-/y}$) and GABAergic neuron-specific MeCP2 deficiency (*Viaat-Mecp2*$^{-/y}$) that recapitulate nearly all major RTT features. We used the *vesicular inhibitory amino acid transporter* (*Viaat*) promoter to express ribosomal protein L10 fused to enhanced green fluorescent protein (*Viaat-L10FP*) in GABAergic neurons for enrichment of actively transcribed mRNA specifically from GABAergic neurons. We compared cortical GABAergic neuron specific gene expression profiles from *Mecp2*$^{-/y}$ and *Viaat-Mecp2*$^{-/y}$ models and found that the majority of transcriptional alterations are not shared between the two models, suggesting that GABAergic specific transcriptional alterations associated with loss of MeCP2 may be

predominantly influenced by the cellular context of MeCP2 deficiency. These findings will enable us to identify primary transcriptional changes associated with MeCP2 deficiency in GABAergic specific neurons, examine the role of the cellular context of MeCP2 deficiency on transcription, and could provide an avenue to further elucidate MeCP2 function in GABAergic neurons and RTT pathogenesis.

Title: Maternal immune activation impairs the maternal-fetal leukemia inhibitory factor signal relay and reduces neural stem/progenitor cell proliferation

Authors: *T. TSUKADA[1], E. SIMAMURA[2], H. SHIMADA[2], T. AKAI[3], H. IIZUKA[3], T. HATTA[2];
[1]neurosurgery, Kanazawa Med. Univ., Isikawa, Japan; [2]Anat., [3]Neurosurg., Kanazawa Med. Univ., Ishikawa, Japan

Abstract: Epidemiological studies suggest that maternal infection increases the risk of schizophrenia and autism in human offspring. Further, recent studies suggest that maternal immune activation (MIA) by infection is a cause of schizophrenia and autism in rodent offspring. Interleukin-6 (IL-6) induced by MIA is a possible key mediator of the effects of MIA on fetal brain development. However, the effects of maternal IL-6 on fetal neurogenesis are unclear. We previously showed that the maternal-fetal leukemia inhibitory factor (LIF)-adrenocorticotropic hormone (ACTH)-LIF signaling relay pathway (the maternal-fetal LIF signal relay) promotes fetal neurogenesis via the placenta in rats. We hypothesized that MIA-induced IL-6 expression in dams interferes with the maternal-fetal LIF signal relay , resulting in insufficient fetal brain development. In this study, we examined an alteration in the maternal-fetal LIF signal relay and neural stem/progenitor cell proliferation affected by MIA in mice (C57BL/6J). Polyriboinosinic-polyribocytidylic acid (polyI:C), a synthetic analog of double-stranded RNA, was used to induce

MIA. Pregnant dams were intraperitoneally injected with 20 mg/kg polyI:C at 12.5 days postcoitum (dpc). Expression of *Pomc* and *SOCS3* in placenta was examined using a gene expression assay, and quantitative PCR was performed 3 h after the injection. Concentrations of ACTH and LIF in fetal serum (FS) and that of LIF in fetal cerebrospinal fluid (CSF) were measured by ELISA at 3 h, and the concentrations of ACTH in FS and LIF in fetal CSF were also measured at 24 h after the injection. At 3 h after the injection, the mRNA level of *Pomc* in the placenta and the concentration of ACTH appeared to reduce, whereas there was no difference in the concentrations of LIF in FS and LIF in fetal CSF compared with the control. At 24 h after the injection, the concentrations of ACTH in FS and LIF in fetal CSF were both reduced. At both time points, the expression of *SOCS3* was upregulated. Using the 5-ethynyl-2'-deoxyuridine, we assessed the neural stem cell/progenitor cell proliferation at 14.5 dpc. Reduction in neural stem/progenitor cell proliferation was observed. Thus, polyI:C injection at 12.5 dpc altered the mRNA level of *Pomc* in the placenta as well as the concentrations of ACTH in FS and LIF in fetal CSF and decreased neural stem/progenitor cell proliferation. These data suggest that maternal-fetal LIF signal relay is affected by MIA, which causes impairment in neural development of fetuses.

Title: Cerebrolysin recovers behavioral and physiological impairments in an environmental rat model of autism

Authors: *A. ZWIERZCHOWSKI-ZARATE[1], S. ROYCHOWDHURY[1,2], A. BANERJEE[1], I. OGOBUIRO[1], G. FLORES[3], M. ATZORI[1,4];

Autonoma de Puebla, Puebla, Mexico; [4]Inst. de Fisica, Univ. Autonoma de San Luis Potosi, San Luis Potosi, Mexico

Abstract: Cerebrolysin (CBL), a nootropic drug used in Europe to treat strokes and conditions with underlying cholinergic deficits. Cerebrolysin has been proposed as a treatment for

developmental conditions like schizophrenia and diseases of the autistic spectrum disorder (ASD). Prenatal injections of valproic acid (VPA) were used as an environmental model of autism. We studied behavioral and physiologic responses in the offspring of pregnant rats injected with saline or VPA at prenatal day 12.5. The offspring of each group was split in two subgroups each, one was given chronic injections of CBL (2.5 ml/kg) and the other was treated with saline for 2 weeks.
Behavioral assays consisted in: social behavior in an open field, Y maze, and elevated plus maze. Rats were treated from P45-P60 and tested on all behavioral assays for 30 days after the injections concluded. Electrophysiological test consisted in the determination of the strength of GABAA receptor-mediated electrically evoked inhibitory postsynaptic currents currents (eIPSCs). We measured the saturation current of input/output stimulus response curves as well as the mean frequency, amplitude, and kinetics of miniature IPSCs recorded in the presence of the Na-channel blocker tetrodotoxin, in a temporal cortex slice preparation, using whole-cell patch clamp from layer II/III pyramidal neurons. We also determined the eIPSC modulation by the muscarinic agonist oxotremorine and by norepinephrine.
As expected from previous studies, the VPA injected offspring displayed impairment in all the behavioral and physiological assays used in the study. Cerebrolysin treatment recovered fully or at least partly almost all the behavioral as well as physiological alteration detected in the VPA offspring, compared to the VPA offspring untreated group, measured between 2 and four weeks after the treatment. These results suggest CBL to have potential use as a pharmacological agent for the treatment of ASD. Further studies should be conducted to determine long-term efficacy and proper treatment dose for ASD patients.

Title: Study of new candidate genes that may have critical role for autism and also schizophrenia

Authors: *K. KOIZUMI[1], M. ITO[1], K. NAKAO[2], H. NAKAJIMA[3];
[1]Ctr. for Child Mental Develop., Kanazawa Univ., Kanazawa-Shi, Japan; [2]Dept. of Physiol., Saitama Med. Univ., Moroyama-Cho, Japan; [3]Ctr. for AIDS Res., Kumamoto Univ., Kumamoto-Shi, Japan

Abstract: Numbers of studies indicate human developmental disorders such as autism and mental retardation are mainly caused by minor dysfunctions of various genes. However, little is known about genes networks that cause neural dysfunction in cognitive development during childhood. We have been trying to identify new candidates critical for human developmental disorders by screening Drosophila and mouse genes involved in neural development.
Here we focus on new candidates, Fam107A/B that may have functions to modify actin assembly. A recent work from other group indicates Fam107A is a stress (maternal separation) response gene that alters spine density in the hippocampus. Over expression of Fam107A improves cognitive behavior such as spatial memory (Schmidt et al, PNAS, 2011). These data suggest Fam107A may have a critical role for human cognitive development. The other gene Fam107B (we call it as "Hit") is a homologous gene that have a same functional domain with Fam107B but little is known about its function in the nervous system. Using neuron-like cell line, PC12 and mouse neural primary cells, we are studying functions of these genes in vitro. Neurite outgrowth study in both PC12 and primary neurons showed FAM107B inhibits neurite outgrowth by over expression. Transwell assay showed over expression of both FAM107A/B change PC12 cells migration induced by NGF. Co-localization of F-actin and FAM107A or B was observed in outer membrane ruffles after NGF induction. To study in vivo function, we also tried gene transferring of FAM107B in utero that caused cortex migration defects. These data suggest FAM107A/B have similar but independent molecular functions in neurite extension & migration.

Title: A new rodent model of cerebral palsy based on prenatal ischemia and abnormal experience

Authors: M. DELCOUR[1], V. S. MASSICOTTE[3], M. RUSSIER[2], M. AMIN[3], O. BAUD[4], *M. F. BARBE[5], J.-O. COQ[2];

Abstract: Cerebral palsy (CP) corresponds to various motor, sensory and cognitive disorders related to white matter damage (i.e. periventricular leucomalacia) often occurring after perinatal hypoxic-ischemic events. To reproduce PVL in rodents, we used a prenatal ischemia (PI) that induces white and gray matter damage. The ischemic rats exhibit visual-spatial cognitive deficits and hyperactivity, as observed in patients with CP, related to lesions of entorhinal, prefrontal and cingular cortices. Only mild locomotor disorders are induced by PI, associated to signs of spasticity, along with anatomical and functional degradation in the primary somatosensory cortex (S1), while the primary motor cortex (M1) remains unchanged. Thus, PI recapitulates the main symptoms found in children born preterm. Abnormal spontaneous movements (i.e. general movements) observed in infants who develop CP later on suggest that abnormal sensorimotor experience during maturation is key in the development of this catastrophic disease. The combination of a sensorimotor restriction (SMR) and PI in animal induces fewer cognitive deficits but still hyperactivity. Such a combination leads to severe postural and motor disorders, and spasticity, associated with musculoskeletal pathologies, as observed in patients with CP. In addition to motor disorders, drastic topographical disorganization of cortical maps in S1 and M1 suggest a major dysfunction of sensorimotor loops. Thus, our rodent model reproduces white and gray matter damage as well as the major CP symptoms. This model also shows that CP not only results from perinatal cerebral damage but from interplay between such lesions and subsequent abnormal sensorimotor experience that both contributes to increase and maintain brain dysfunctions and lesion, and in fine motor disorders, through impairments of sensorimotor integrative loops. Our promising model of CP may be valuable for exploring new strategies to prevent damage and maladaptative plasticity in immature brain.

Title: Disruption of protein homeostasis by autophagy deficiency leads to aggregation of disease-associated proteins and abnormal psychiatric behaviours

Authors: *K. K. HUI[1], A. WATANABE[2], H. MATSUKAWA[3], P. NILSSON[4], T. C. SAIDO[4], S. ITOHARA[3], T. YOSHIKAWA[2], M. TANAKA[1];
[1]Lab. for Protein Conformation Dis., [2]Lab. for Mol. Psychiatry, [3]Lab. for Behavioral Genet., [4]Lab. for Proteolytic Neurosci., RIKEN Brain Sci. Inst., Wakoshi, Japan

Abstract: Although next-generation sequencing methods have enabled researchers to perform genome-wide association studies (GWAS) and examine the genetic origins of psychiatric disorders such as schizophrenia and autistic spectrum disorder (ASD), no single genetic factor have been identified to be strongly linked with either disease, therefore suggesting they are complex disorders in which multiple proteins and/or signalling pathways may be involved. Given the complex nature of these psychiatric disorders, we hypothesize that misfolding and aggregation of disease-associated proteins may play a critical role in their pathogenic mechanisms as multiple proteins may be affected simultaneously. As such, we have utilized autophagy deficiency (conditional deletion of *Atg7*) as a strategy to disrupt protein homeostasis, thereby increasing the accumulation of misfolded and aggregated protein.
We have observed that autophagy deficiency in forebrain excitatory neurons led to the accumulation of p62- and ubiquitin-positive aggregates as previously shown in other constitutive and conditional *Atg7* conditional knockout (cKO) mice. Interestingly, many disease-associated proteins were contained within these aggregates and were found to be increased in the detergent-insoluble fraction. Consistent with a reduction in the functional pool of affected proteins due to aggregation, functional assays and dendritic spine density analysis revealed significant reductions in *Atg7* cKO mice. Accordingly, deficits in long-term potentiation and other electrophysiology parameters were also observed in *Atg7* cKO mice. At the whole animal level, behavioural analysis reveals disturbances in behaviours associated with autistic spectrum disorder and schizophrenia.
The current study reveals for the first time that multiple disease-associated proteins are aggregation-prone as a result of disrupted protein homeostasis, and the resulting reduction of functional proteins may underlie the neuronal dysfunction and behavioural abnormalities. Along with recent findings from other laboratories, additional studies are warranted to provide further

evidence to support the hypothesis that protein misfolding and aggregation may be involved in the pathogenesis of psychiatric disorders such as ASD and schizophrenia.

Title: A mouse model for too much TV: Unraveling the mechanisms and developmental differences in the response to sensory overstimulation

Authors: J. S. B. RAMIREZ[1], D. A. CHRISTAKIS[1,3], R. D. HODGE[2,3], R. F. HEVNER[2,3], *S. RAVINDER[4], T. K. M. RAMIREZ[1], A. F. SMITH[1], M. F. BURGOS[2], J. M. RAMIREZ[2,3]; [1]Child Hlth. Behavior and Develop., [2]Ctr. For Intigrative Brain Res., Seattle Children's Res. Inst., Seattle, WA; [3]Univ. Of Washington, Seattle, WA; [4]Ctr. For Integrative Brain Res., Seattle, WA

Abstract: With the rapid rise in media use over the past decade, infants are exposed to an influx of fast-paced sensory stimuli ranging from excessive television viewing to touchscreen applications on their mobile devices. This form of sensory overstimulation can lead to detrimental behavioral as well as neuronal changes during development. We tested this hypothesis in a mouse model in which mice (P10 - neonatal or p60 - adults) were exposed to auditory stimuli taken from the cartoon network channel and pared with visual overstimulation. Mice were stimulated for six hours per day for a total of 42 days. Overstimulation during their neonatal time period had detrimental effects resulting in diminished cognition, hyperactivity and increased risk taking (Christakis et al. 2012). Here we demonstrate, that there is a critical window in development during which the overstimulation has its greatest effects. We investigated this issue by characterizing the behavior and underlying neuronal mechanisms. Our results indicate that mice had significantly different behavioral results depending on when they were overstimulated. Moreover adult neurogenesis in the dentate gyrus was reduced in mice that were overstimulated as neonates, but there were no differences in mice that were overstimulated as adults. Our ongoing electrophysiological and optogenetic characterizations may reveal that hippocampal and amygdala activity is altered following non-normative sensory overstimulation in neonates, but not adults.

Title: Different subcellular distributions of AMPA and NMDA receptor subunits in two rat models of cognitive dysfunctions

Authors: A. K. LEE[1], K. S. DERVOLA[1], V. JENSEN[2], B. A. ROBERG[1], M. J. NIELSEN[1], P. STRØMME[3], Ø. C. HVALBY[2], *S. WALAAS[1];
[1]Biochem., [2]Physiol., Univ. of Oslo, Oslo, Norway; [3]Pediatrics, Oslo Univ. Hosp., Oslo, Norway

Abstract: Many cognitive functions appear to depend on intact glutamatergic neurotransmission in hippocampal synapses, but the extent to which specific molecular changes in these synapses are related to specific functional deficits remains unclear. The spontaneously hypertensive rat (SHR) and the inattentive ADD rat (WKY-NCrI) have been proposed as animal models for subtypes of human cognitive disorders (Sagvolden et al., 2009). We have examined the subcellular distribution of the A1 and A2 subunits from the glutamate (Glu) α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors as well as the N1 subunit from the N-methyl-D-aspartic acid (NMDA) receptors, together with the postsynaptic density (PSD) marker protein PSD-95 and the cytoskeleton marker β-actin, in hippocampi from these strains and from control rats (WKY-strain). Hippocampal slices were dissected and stabilized in ACSF, followed by biotinylation to label surface proteins. Subcellular fractions were prepared and analysed by immunoblotting with specific antibodies. The Glu receptor subunits showed different distribution patterns. In the WKY controls, both the A1 and A2 subunits were enriched in the extrasynaptic membrane and cytosolic fractions, with only ~10% present in the intrasynaptic PSD fraction, whereas the N1 subunit was enriched in the PSD fraction, similar to the PSD-95 protein. Specific changes were found in the SHR and ADD animals. In the SHR animals, both A1 and A2 subunits showed decreased levels restricted to the PSD fractions, whereas the N1 subunit was unchanged in all fractions. In the ADD animal, no changes were seen in the A1 subunit, whereas

A2 subunit levels were enhanced in the PSD fraction, but decreased in the extrasynaptic membranes. Finally, levels of the N1 subunit were decreased in the PSD fraction, comparable to a 50% decrease in β-actin found in the same fraction. Our data therefore indicate that the hippocampi from the SHR and ADD rat strains have important differences in their subcellular organization, both of the glutamatergic AMPA and NMDA receptor subunits and also of the interaction between the spine cytoskeleton and PSD components. Such differences may be related to the distinct cognitive phenotypes found in these animal models.

Title: Behavioral impact of *In utero* exposure to valproic acid in adult female mice

Authors: R. F. MARTIN[1], B. K. KRUEGER[2], *E. M. POWELL[1];
[1]Anat/Neurobio, [2]Physiol., Univ. Maryland, Baltimore, BALTIMORE, MD

Abstract: Valproic acid (VPA) is a drug used primarily in the treatment of epilepsy, but is also effective in treating bipolar disorder. Pregnant mothers taking VPA have an increased risk of giving birth to children with low IQ, delays in language and abnormal social interaction, characteristics that are associated with autism. Exposure to VPA in the late first trimester seems to present the greatest risk for developmental problems.
In the mouse, a single dose of VPA at E12.5 can produce offspring with behavioral impairments similar to those seen in autism. In this study, we hypothesize that fetal exposure to VPA alters cortical neurogenesis and/or neuronal migration, subsequently leading to impaired behavior and cognition. Previous work from our lab revealed differences in anxiety between the mice treated with VPA and those treated with vehicle control in a mostly male cohort. Sex differences were apparent, so we tested a larger female cohort. We administered several behavioral tasks to adult female mice exposed to VPA in utero to measure anxiety, motor function and general behavior, and social interaction. Overall, compared to females given vehicle in utero, there was a decrease in anxiety in females exposed to VPA. We also observed increased stereotypical behavior in both male and female offspring. These results were comparable to our previous work, demonstrating

that offspring of pregnant dams treated with VPA exhibit a behavioral phenotype similar to that observed in human offspring of mothers treated with VPA.

Title: The guinea pig as a translational model for lifespan behavioral development

Authors: *G. A. KLEVEN, D. LUCAS, J. S. BREWER;
Psychology, Wright State Univ., Dayton, OH

Abstract: Although several excellent non-mammalian models of lifespan behavioral development exist, many studies of early neural insult and developmental disabilities require a mammalian model in order to examine changes across development in placental or maternal-fetal systems. Current mammalian models of lifespan development are either cross-sectional (rodents such as rats and mice), or prohibitively expensive for teratological studies (large mammals such as sheep or non-human primates). In this study we chose the laboratory guinea pig, *Cavia porcellus*, because of the many similarities this species shares with humans during pregnancy, precocial offspring, and social development. Using innovative methods of behavioral acclimation to ultrasonography, prenatal offspring of female IAF hairless guinea pigs (Charles River, Kingston) time mated to NIH multi-colored Hartley males (Elm Hill Labs, Chelmsford, MA) were observed longitudinally with ultrasound (GE Voluson 730 Expert) at weekly intervals across a 10 week gestation. To insure that the ultrasound procedure did not cause significant stress, salivary cortisol was collected both before and immediately after each of the observations. Measures of fetal spontaneous movement and behavioral state were quantified from video recordings from the beginning of movement at week 3 through the last week before birth. During ultrasound observations, the location of each fetus was also noted, and these individual subjects were then identified during the birth process. Postnatal offspring were observed in a series of behavioral tests, including open field and social interaction. Results from prenatal quantification of Interlimb Movement Synchrony and state organization reveal guinea pig fetal development to

be strikingly similar to that previously reported for the human fetus and preterm human infant. Consequently, this longitudinal model holds great translational promise for studying the mechanisms of developmental disabilities. More specifically, because the guinea pig is a highly social mammal, with a wide range of socially oriented vocalizations, this model may also have utility for studying the trajectories of developmental disabilities with social-emotional and/or language deficits, such as autism.

Title: Adolescent olanzapine treatment alters behavior and cortical and subcortical reorganization in adult rats

Authors: *S. RAZA[1], A. MUHAMMAD[1], R. MYCHASIUK[1], D. O. FROST[2], B. KOLB[1]; [1]Univ. of Lethbridge, Lethbridge, AB, Canada; [2]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: There is an increasing widespread use of olanzapine (OLA), an atypical antipsychotic drug, among children and adolescent populations to treat a variety of psychiatric disorders. While most animal studies, aimed at characterizing the functional sequelae of early OLA exposure, have focused primarily on developmental stages, there has been little examination of how this experience influences long-term outcomes. The present study examined the anatomical and behavioral sequelae following OLA treatment in adolescent rats. Adolescent male rats received OLA or a vehicle on postnatal days 28-49. In adulthood, rats were tested on the object/context mismatch paradigm of the novel object recognition task. Findings revealed behavioral changes associated with adolescent OLA exposure. That is, OLA-treated animals explored the novel object considerably less, relative to the vehicle group, thereby demonstrating a deficit in processing contextual information. In addition, these behavioral changes were

accompanied with alterations in the dendritic architecture of the medial and orbital prefrontal cortices and nucleus accumbens. Such findings demonstrate the consequent long-term anatomical and behavioral modulation of early OLA exposure in rats. This may have significant implications in assessing the enduring behavioral, neurobiological, and safety of OLA exposure during development.

Title: Folate deficiency: Elucidating the role of an epigenetic risk factor in developmental disorders in mice

Authors: *L. SCHAEVITZ[1], L. PAUL[2], J. SELHUB[2], J. E. BERGER-SWEENEY[1]; [1]Tufts Univ., Medford, MA; [2]Tufts Univ., Boston, MA

Abstract: One carbon (C1) metabolism plays a critical role in establishing and maintaining DNA methylation throughout life making it a promising candidate pathway to regulate epigenetic programming in developmental disorders including autism (ASD) and schizophrenia (SZ). Epidemiological studies provide evidence that increased risk for ASD and SZ is associated with both polymorphisms in C1 metabolic genes and nutritional deficiencies in C1 substrates, including folate, in both the mother and the affected offspring. Given the challenge of assessing nutritional status across the lifespan in humans, it is difficult to identify clinical symptoms that may be attributed to folate deficiency in utero (from the mother) as compared to folate deficiencies restricted to childhood or adulthood. Knowing critical time periods in susceptibility to folate deficiences can aid in understanding the etiology of and developing treatment strategies for specific symptoms of ASD and SZ. Previously we showed motor deficits, social withdrawal and cognitive dysfunction in post-weaning folate-deprived mice (Schaevitz et al., Dev Neurosci, 2012). In this study, we hypothesize that maternal folate deficiency will result in broader behavioral abnormalities as compared to post-weaning deprivation. C57Bl/6J female mice were fed a control (2 mg/kg) or folic acid deficient diet (0.4 mg/kg) for 6 weeks prior to and throughout pregnancy and lactation. Offspring were on the mother's diet until weaning. At

weaning, all offspring were fed a control diet and assessed as adults on a behavioral battery to examine repetitive/stereotyped, motor, social, anxiety, and cognitive function; behaviors affected in ASD and SZ. Adult offspring from folate-deficient mothers are less social and exhibit cognitive deficits, suggesting that early folate deficiency leads to long-lasting changes in brain function similar to those elicited by post-weaning folate deficiency. To elucidate potential molecular pathways through which altered folate metabolism affects behavior, the expression of a number of candidate proteins implicated in both ASD and SZ were examined in the prefrontal cortex. The expression of proteins involved in GABAergic function is significantly decreased in the adult offspring of folate-deficient mothers compared to the offspring of control mothers. We are currently investigating whether early folate deprivation leads to gene-specific changes in DNA methylation resulting in the dysregulated expression of proteins in the GABAergic pathway.

Title: Fluoxetine administered to juvenile monkeys upregulates the serotonin transporter and alters behavior into early adulthood

Authors: *S. SHRESTHA[1,2];
[1]Natl. Inst. of Mental Hlth., NIH, Bethesda, MD; [2]Karolinska Institutet, Stockholm, Sweden

Abstract: Abstract
Objective: The use of antidepressants in children is controversial because of possible long-lasting effects on the developing brain. This study examined the long-term effects of fluoxetine administered to juvenile rhesus monkeys who, as young adults, were imaged with positron emission tomography (PET) for two serotonergic markers: serotonin transporter (SERT) and serotonin 1A (5-HT1A) receptor. An equal number of monkeys separated from their mothers at birth_an animal model of human childhood stress_were also studied.
Method: At birth, 32 male rhesus monkeys were randomly assigned to either maternal separation or normal rearing conditions. At age two, half (N = 8) of each group was randomly assigned to fluoxetine (3 mg/kg) or placebo for one year. To eliminate the confounding effects of residual

drug in the brain, monkeys were scanned at least 1.5 years after drug washout. Social interactions both during and after drug administration were also assessed.
Results: Fluoxetine persistently upregulated SERT, but not 5-HT1A receptors, in both neocortex and hippocampus. Whole-brain, voxel-wise analysis found that fluoxetine had a statistically significant effect in lateral temporal and cingulate cortices. In contrast, neither maternal separation by itself nor rearing-by-drug interaction was statistically significant for either SERT or the 5-HT1A receptor. Fluoxetine decreased dominance and increased submissive displays into adulthood in both rearing groups.
Conclusion: Fluoxetine administered to juvenile monkeys upregulates SERT and decreases dominance-like behaviors into young adulthood. This study is the first in nonhuman primates to demonstrate that an antidepressant administered during development has persistent effects into adulthood.

Title: BUM5, a lipophilic prodrug of bumetanide but not bumetanide itself enhances the anticonvulsant effect of the GABAmimetic drug phenobarbital in epileptic mice

Authors: *C. BRANDT[1,2], K. TÖLLNER[3,2], F. TWELE[3,2], G. BRUNHOFER[4], T. ERKER[4], M. GABRIEL[4], W. LÖSCHER[3,2];
[1]Univ. of Vet. Medicine/Dept. of Pharmacol., Hannover, Germany; [2]Ctr. for Systems Neurosci., Hannover, Germany; [3]Dept. of Pharmacol., Univ. of Vet. Med., Hannover, Germany; [4]Dept. of Medicinal Chem., Univ. of Vienna, Vienna, Austria

Abstract: Rational: Recent studies demonstrate a possible role of cation-chloride-co-transporters in the pathogenesis of epilepsy. Changes in the expression pattern of the K+-Cl- co-transporter KCC2 (downregulation) and the Na+-K+-2Cl- co-transporter NKCC1 (upregulation) lead to a

GABA-shift from a hyperpolarizing to a depolarizing action caused by an accumulation of intracellular chloride. This results in a hyperexcitatory state of specific networks. In this respect the diuretic drug bumetanide has attracted growing interest. Bumetanide is an inhibitor of NKCC1 so that it is assumed that the administration of bumetanide could counteract the shift to a depolarising GABA action. Two major drawbacks of bumetanide, the diuretic potential and the low brain penetration restrict the testing of bumetanide in experimental and clinical settings.
Aim: The aim of the study is to investigate the effect of bumetanide´s prodrug BUM5 on the GABAmimetic anticonvulsant drug phenobarbital (PB) in epileptic mice. BUM5 was designed to be more lipophilic in order to penetrate into the brain and be less diuretic than bumetanide.
Methods: Drug trials were performed once a week in female NMRI mice in the maximal electroshock threshold test (MEST) beginning six weeks after a pilocarpine induced status epilepticus (SE). PB was tested alone or in combination with bumetanide or BUM5 at a dosage of 10 mg/kg i.p. with a pretreatment time of 30 min. Bumetanide (10 mg/kg i.v.) or BUM5 (13 mg/kg or 1.3 mg/kg i.v., equimolar to bumetanide) were administered 30 min before PB injection. A group of control mice without SE underwent the same test schedule.
Results: PB alone increased the seizure threshold by approx. 30% in both, control and epileptic mice. Bumetanide (10 mg/kg) and BUM 5 (1 mg/kg) did not effect the anticonvulsant effect of PB. However, at 10 mg/kg, BUM5 more than doubled the anticonvulsant effect of PB in epileptic mice, whereas such an effect was not seen in nonepileptic controls.
Conclusions: The results of this study indicate that the lipophilic prodrug of bumetanide, BUM5, could be a useful tool to study the role of NKCC1 in the pathogenesis of epilepsy and also offers a treatment option superior to the treatment with bumetanide.

Title: Bexarotene decreases hyperexcitability in two mouse models with epilepsy

Authors: *V. C. BOMBEN[1], J. K. HOLTH[1], P. E. CRAMER[2], G. E. LANDRETH[2], J. L. NOEBELS[1];
[1]Neurol., Baylor Col. of Med., Houston, TX; [2]Neurosciences, Case Western Reserve Univ., Cleveland, OH

Abstract: Epilepsy is a complex disease with diverse environmental and genetic causes, including mutations in many ion channel genes. Moreover, epilepsy is often co-morbid with other neurological diseases such as Alzheimer's disease (AD). This makes understanding the common mechanisms between these diseases an excellent way to advance both fields of study. Recently, a cancer drug and specific retinoid X receptor agonist, bexarotene, has been shown to have a beneficial impact on a mouse model of Alzheimer's disease by reducing amyloid beta levels and improving cognitive deficits. However, the effect of bexarotene on the known neuronal network hyperexcitability of Alzheimer's mouse models has not previously been investigated, and could shed light on intermediary pathogenic mechanisms. We examined the effects of bexarotene on spontaneous cortical activity patterns in the J20 human APP mouse model of AD by EEG monitoring in awake, behaving mice. We observed that continuous oral treatment with bexarotene reduced the interictal EEG spike rate in the J20 mouse model aged 6 to 12 months. In order to further investigate this hyperexcitability reduction, we next studied a well described mouse model of epilepsy, the knockout of the voltage gated potassium channel Kv1.1. Although the Kv1.1 model does not express amyloid beta plaque pathology as seen in the J20 model, we observed by video EEG that hyperexcitabiliy, as measured by interictal spike rate, decreased over a similar course of bexarotene treatment. The effects of bexarotene progressed over several days, and were reversible. When acute hippocampal slices were bathed in 7.5mM KCl to elicit synchronous spikes within the CA3 neuronal layer, application of 10 [[Unsupported Character - Symbol Font ]]M bexarotene elicited a small but significant decrease in the spontaneous spike rate. Taken together, the in vivo and ex vivo decreases in hyperexcitability in models with and without amyloid beta plaque pathology raises important implications for understanding the mechanisms and benefits of bexarotene as a cognitive enhancer. (Research supported by NIH T32NS043124-09 and the Extendicare Foundation).

Title: The phytocannabinoid cannabidivarin demonstrates notable antiepileptic properties and is a genuine candidate for the treatment of temporal lobe epilepsy

Authors: *I. A. A. PÉRÈS[1,2], R. HADID[3,2], N. AMADA[3], C. L. HILL[3], A. ALHUSAINI[3], A. J. HILL[3], C. M. WILLIAMS[2], B. J. WHALLEY[3];

Abstract: Epilepsy is a chronic and debilitating neurological condition characterised by recurrent seizures; 50 million people worldwide are affected. Temporal lobe epilepsy (TLE) is the most common epilepsy and one of the most refractory to existing medicines; ≥30% of patients are unresponsive to antiepileptic drugs (AEDs) while 20% have limited seizure control. Currently available AEDs have significant side-effects, adversely affecting alertness, motor control and cognition, making more efficacious and better tolerated AEDs an urgent requirement. Growing evidence from pre-clinical research on marijuana-derived compounds, and self-medication by epilepsy patients with marijuana, support the study of phytocannabinoids as new AEDs.
Here, the antiepileptic and tolerability profiles of a non-psychoactive phytocannabinoid, cannabidivarin (CBDV) were assessed. The lithium pilocarpine model of TLE was used to induce spontaneous recurrent seizures in male Wistar rats. Animals were treated with 200 mg/kg/day CBDV for 12 weeks and effects on seizure frequency and severity were behaviourally assessed daily for 3 weeks. CBDV significantly reduced both severe seizure incidence and seizure index (seizure severity x seizure frequency). Tolerability was assessed using static beam, grip strength and inclined screen tasks, where CBDV produced no motor function deficits or neurotoxicity. CBDV also attenuated motor function deficits observed in epileptic animals, further supporting its antiepileptic effects. Finally, electrocorticography (ECoG) recordings were used to assess the effects of acute CBDV administration (200 mg/kg) on baseline (non-seizure) neuronal activity of epileptic and non-epileptic animals. CBDV exerted few effects upon the power spectra of signals recorded from hippocampus and parietal cortex, further supporting CBDV's tolerability. In conclusion, CBDV has significant antiepileptic properties and is extremely well tolerated, supporting CBDV as a genuine candidate for the treatment of human TLE.

Title: Inhibitory action of levetiracetam on CA1 population spikes and dentate gyrus excitatory transmission in pilocarpine-treated chronic epileptic rats

Authors: *E. G. SANABRIA[1], L. PACHECO[1], J. ZAVALETA[1], F. SHRIVER[1], L. M. RAMBO[2], C. UPRETI[3], P. K. STANTON[3];
[1]Biomedicine, Univ. of Texas Brownsville, BROWNSVILLE, TX; [2]Dept. de Fisiologia e Farmacologia, Univ. Federal de Santa Maria, Santa Maria, Brazil; [3]Cell Biol. & Anatatomy, Dept. Neurol., New York Med. Col., Valhalla, NY

Abstract: The presynaptic target for Levetiracetam (LEV) has been identified as synaptic vesicle SV2A proteins in presynaptic terminals; however, the mechanisms of LEV's antiepileptic action remain unclear. Previous studies have shown a reduction of SV2A expression in both animal models and human suffering mesial temporal lobe epilepsy (MTLE). However, in vivo treatment with LEV appears to be still effective in those conditions in ameliorating seizures. In this study, we evaluated the in vitro effects of LEV on excitability and excitatory synaptic transmission in the pilocarpine model of mesial temporal lobe epilepsy (MTLE). In this study, we investigated the action of LEV on (a) population spikes recorded in CA1 area and (b) excitatory synaptic transmission onto dentate gyrus of control versus chronically epileptic rats obtained by the pilocarpine model of MTLE. For this purpose, we used extracellular potential recordings in acutely dissociated slices. Slices were pre-incubated in 300 microM of LEV for 3 hours prior recordings. LEV was also applied in the bath during recording sections. Field excitatory postsynaptic potentials (fEPSP) were evoked by different paradigms of repetitive stimuli of perforant path (e.g. 10@20Hz). Pre-incubation with LEV induced a 20% and 10% reduction in amplitude of CA1 population spikes in slices from control and epileptic rats respectively relative to non-treated slices. LEV induced a 37.2% and 49% significant reduction in the amplitude of the summated fEPSPs in a 20Hz train evoked by perforant path stimulations in both control and epileptic groups respectively ($df=9$, $p< 0.0001$ by paired T-test) compare to baseline. Significant changes were also detected in the first four fEPSP responses in the train with a non-significant reduction of remaining 6 fEPSPs (ANOVA repetitive Test, $p<0.01$ for both groups followed by pairwise Tukey post-hoc test). These results indicate that LEV is effective in reducing in vitro excitability and excitatory synaptic transmission in both control and epileptic groups (despite possible changes in SV2A expression). Further studies are in progress to determine presynaptic mechanisms involved in this inhibitory effect.

Title: Fish oil provides protection against the oxidative stress in the animal model of epilepsy induced by pilocarpine

Authors: *M. B. NEJM[1,1], A. A. HAIDAR[1], A. E. HIRATA[1], R. M. CYSNEIROS[2], E. A. CAVALHEIRO[1], F. A. SCORZA[1];
[1]Federal Univ. of Sao Paulo, Sao Paulo, Brazil; [2]Mackenzie Presbyterian Univ., São Paulo, Brazil

Abstract: Temporal lobe epilepsy (TLE) is the most common form of epilepsy in humans and often resistant to pharmacological treatment. The pilocarpine model has been widely used due to similarity with the TLE in humans. Evidence points to the fact that neuronal lesions seen in epileptic seizures may be the result of an overproduction of free radicals (oxidative stress). Such evidence includes a positive correlation between the time of free radicals formation and the development of seizures, the protective effect that treatment with some antioxidants showed and also revealed findings such as increased lipid peroxidation. Oxidative stress is characterized by an imbalance between the antioxidant defenses and the oxidizing agents (free radicals), which can lead to tissue injury. The n-3 PUFAs are important for the development and maintenance of central nervous system functions. Our laboratory data demonstrated that chronic treatment with fish oil, immediately after status epilepticus (SE) exhibited neuroprotective and neuroplastic effects. The main propose of this research was to evaluate if n-3 PUFAS can also exhibits a protective effect against oxidative stress. Animals were subjected to the animal model of TLE by pilocarpine administration (350 mg/kg, i.p) and the controls received saline. After 3h of SE the animals were randomly divided into the following groups: animals with epilepsy treated daily with vehicle (PV) or with 85mg/kg of fish oil (PW), control animals treated daily with vehicle (CV) or with 85mg/kg of fish oil (CW). After 90 days, the enzymatic activity of superoxide dismutase (SOD), catalase (CAT) and glutatione peroxidase (GPx) were investigate in serum and hippocampus and the expression of the SOD, CAT and NAD(P)H oxidase subunits p47 and gp91

were analyzed by western blot in hippocampus. The enzymatic activity of CAT in hippocampus, SOD and GPx in serum significantly increased in PW group comparatively to other groups, with no changes in all protein expression analysed. This finding suggests that supplementation with fish oil can provide protection against oxidative stress by increasing the activity of antioxidant enzymes.

Title: Anticonvulsant effects of α-terpineol isolated from myristica fragrans on epileptic rat models and its inhibitory activity on GABAA receptor modulators in xenopus oocytes

Authors: *J. M. ABDULLAH, Prof[1], M. R. ISLAM[1,3], C. H. TARMIZI[1], H. OSMAN[2]; [1]Dept of Neurosciences, Universiti Sains Malaysia, Kelantan, Malaysia; [2]Sch. of Chem. Sci., Universiti Sains Malaysia, Minden, Malaysia; [3]Anat. and Histology, Bangladesh Agr. Univ., Mymensingh-2202, Bangladesh

Abstract: Medicinal plants continue to play a valuable role in the drug discovery process. Plant extracts can be an important source for the development of better and safer drugs for the treatment of epilepsy. Several plants that were reputed to possess antiepileptic properties in different folklore cultures have been found to exhibit anticonvulsant activities in different animal models. The aim of the present study was to investigate the antiepileptic activity of α-terpineol that isolated from Myristica fragrans Hountt. The nutmeg oil was extracted from kernels of Myristica fragrans by steam distillation and was analysed by gas chromatography-mass spectrometer (GC-MS) method. We have isolated 16 components from extracted nutmeg oil and the α-terpineol was the major components (28.05%) of nutmeg oil. We used three different doses of α-terpineol (10, 20 and 50 mg/kg; intraperitoneally) on epileptic rat models. The α-terpineol significantly reduced the seizure episodes and spikes in absence seizures model of Genetic Absence Epilepsy Rats from Strasbourg (GAERS) rats and kainic acid induced epileptic Sprague Dawley rat model by using electroencephalography (EEG) records (The EEG activity was acquired by Data Sciences International radio-telemetry system and analyzed off-line using

Neuro-Score software (St. Paul, MN, USA)). It showed a rapid onset (within 2 min) and relatively long duration of anticonvulsant effects on animal models. The dose-dependent anticonvulsant effects were comparable to the known antiepileptic drug of diazepam. We have also defined the inhibitory effects of α-terpineol at different concentration in chloride currents (IGABA) stimulation through gamma-amino butyric acid type A (GABAA) receptors comprising of α1β2γ2s subtype activity making use of a two-microelectrode voltage clamp assay on Xenopus laevis oocytes. The α-terpineol was found to be induced an enhancement of IGABA modulation (EC5-10) by 229.6 ± 23.8% and 326.3 ± 43.8%, respectively at 100 μM and 500 μM. Thus the dose dependent activity of α-terpineol showed statistical significance potentiation of IGABA in comparison to the control group. Our present findings thereby provides a scientific evidence for the traditional use of nutmeg oil for the treatment of epilepsy, and suggest that the α-terpineol may deserve to be a potential candidate of antiepileptic compounds.

Title: Determining efficacy of retigabine on acute limbic seizure threshold in adult rats

Authors: *L. K. FRIEDMAN, J. P. WONGVRAVIT, A. M. SLOMKO, S. HU, W. WAN, S. ALI, Z. NASSEER;
Cell Biol. & Anat., New York Med. Col., Valhalla, NY

Abstract: Retigabine (manufactured by GlaxoSmithKline), is the first neuronal potassium channel opener indicated for the adjunctive treatment of focal (partial) seizures in adult patients. However; little is known about the efficacy of retigabine in experimental models of partial limbic seizures. The oral LD50 for rats was previously reported at 980mg/kg. We tested systemic doses of retigabine (1, 2, 5, 10, 100, 300 mg/kg) on kainate (KA)-induced status epilepticus (SE) in adult rats 30 min prior to (and 2 hrs following) injection of KA (16 mg.kg, i.p.). Doses ≥10 mg/kg produced deep, rapid sedation and was discontinued. A single injection of 2 or 5 mg/kg was insufficient to prevent the induction of KA SE; however there was significant reduction or absence of stage5-6 seizure behavior symptoms such as pronounced drooling and forelimb

clonus in 50% of the animals. Two prior treatments (24 hrs and 30 min prior to KA injection) increased seizure behavior latency and attenuated spiking in the electroencephalogram (EEG). At 2 hrs after KA injection, during status epilepticus, 2 mg/kg of retigabine quickly calmed seizure behavior and reduced epileptiform discharges, whereas, 5 mg/kg increased EEG spiking and synchronization of burst activity. Although histological analysis revealed that animals scored with stage5-6 seizures exhibited typical hippocampal injury regardless of treatment, GluR1 subunit protein was selectively suppressed within the granule cell layer (GCL) and the mossy fiber synapse in animals treated with retigabine. Animals treated with retigabine that were resistant to KA-SE did not exhibit significant injury only indicating that retigabine was neuroprotective if seizures were prevented. Thus, it appears that lower doses of retigabine had greater efficacy producing a potent anticonvulsant effect possibly due to reduced excitatory transmission via AMPA receptors; whereas higher doses produced ataxia and proconvulsant effects in this model of epilepsy indicating that the dosage used in humans must be carefully scrutinized to produce the adequate clinical response.

Title: An *in vitro* screen for antiepileptogenic compounds utilizing organotypic hippocampal slice cultures

Authors: *Y. SAPONJIAN[1], Y. BERDICHEVSKY[2], W. SWIERCZ[1], K. STALEY[1]; [1]Neurol., Massachusetts Gen. Hosp., Charlestown, MA; [2]Electrical & Computer Engin., Lehigh Univ., Bethlehem, PA

Abstract: The accelerated course of epileptogenesis in the *in vitro* organotypic hippocampal slice culture model of post-traumatic epilepsy (Dyhrfjeld-Johnsen et al. *J Clin Neurophysiol* 2010) was utilized to conduct a moderate-throughput screen of an array of drugs to study their antiepileptic and neuroprotective effects and ultimately find antiepileptogenic compounds.
Organotypic hippocampal slices cultures were generated from postnatal day 6 or 7 Sprague-Dawley rats and were maintained in poly-D-lysine coated 6-well tissue culture plates on a rocking platform in a humidified chamber at 37^{o}C and 5% CO_2. The culture medium consisted of Neurobasal-A, B27, 0.5 mM GlutaMAX, and 30 μg/ml Gentamicin and was changed every 3-4 days. Drugs, obtained primarily from the NINDS custom Compound Collection, were dissolved in DMSO (final concentration 0.1%) and added to the media starting on DIV 3. All experiments included DMSO control slice cultures derived from the same animal.
The lactate concentration in spent culture medium was strongly correlated with electrographic seizure activity and used in subsequent experiments as an assay for seizure activity. Lactate dehydrogenase concentration in spent culture medium was correlated with propidium iodide assays for cell death and used in subsequent experiments as an assay for the rate of cell death (Berdichevsky et al. *J Neurosci* 2013). Lactate and LDH concentrations were plotted as cumulative values over 28 days *in vitro* for chronic-application experiments.
With these technologies, one researcher was able to screen 9 conditions per week with 3 replications per condition. We investigated culture conditions, culture media components, and the anticonvulsant, antiepileptogenic, and neuroprotective effects of over 150 drugs. Drugs were typically tested at 3 concentrations: the most likely effective concentration as well as 1 log above and below this concentration. Positive screens were repeated to confirm the findings. Drugs exhibiting significant anticonvulsant activity were further analyzed in wash-out experiments to differentiate anticonvulsant from antiepileptogenic effects.
Several drugs exhibited dose-dependent anticonvulsive or proconvulsive effects, as well as neuroprotective or neurotoxic effects. The timing of drug application was an important determinant of the action of several drugs. Anticonvulsant and neuroprotective effects were strongly correlated, presumably due to reductions in ictal cell death. This technology comprises a promising tool for the rapid investigation of drug efficacy in chronic epilepsy.

Title: Ezogabine protects against status epilepticus-induced neurodegeneration and cognitive decline

Authors: *A. B. ALEX[1], S. D. DRAPER[1], K. JOHNSON[1], J. L. FITTS[1], H. S. WHITE[1,2]; [1]Anticonvulsant Drug Develop. Program, Salt Lake City, UT; [2]Pharmacol. and Toxicology, Univ. of Utah, Salt Lake City, UT

Abstract: Status epilepticus (SE) when left untreated leads to long-term consequences that include hippocampal sclerosis, behavioral and cognitive deficits. The cell loss and cognitive decline associated with pilocarpine-induced status epilepticus (SE) is consistent with the sclerosis observed in human temporal lobe epilepsy. Effective therapeutic intervention and suppression of seizures is essential to prevent seizure-induced neurodegeneration and cognitive decline. An ideal anti-seizure drug should not only be able to block the seizures, but also prevent the seizure-induced long-term functional consequences. The present study was undertaken to evaluate the ability of the newly approved anti-seizure drug ezogabine (EZG), to prevent neurodegeneration and subsequent cognitive decline. Systemic administration of pilocarpine (50 mg/kg; i.p.) induces prolonged seizures that last for several hours. Administration of EZG (60 mg/kg) at 30 minutes after the first stage 3 seizure halted the generalized behavioral seizures. Two weeks after SE, the rats were tested for spatial learning and memory in Morris water maze, where the task is to find a hidden escape platform. The rat's escape latency, distance traveled and swim speed were recorded. Pilocarpine alone-treated rats showed significantly higher escape latency and traveled greater distance before finding the platform. The rats treated with EZG, performed better than pilocarpine-treated rats. In addition, administration of EZG prevented the hippocampal cell death in DG, CA3 and CA1 cell layers in a majority of the animals. Results from these studies suggest that EZG, a new anti-seizure drug with a unique mechanism of action; i.e., potassium channel activator, has the potential to be a useful drug in attenuating seizure-induced cognitive decline associated with hippocampal sclerosis.

Title: Cannabidiol and cannabidivarin in a non-psychoactive, well defined marijuana extract exert linearly additive anticonvulsant effects against generalised seizures

Authors: *T. D. HILL[1], M. DUNCAN[3], C. M. WILLIAMS[2], A. J. HILL[1,2], B. J. WHALLEY[1]; [1]Reading Sch. of Pharm., [2]Sch. of Psychology and Clin. Language Sci., Univ. of Reading, Reading, United Kingdom; [3]GW Pharmaceuticals plc, Salisbury, United Kingdom

Abstract: Epilepsy is a chronic neurological disorder characterised by recurrent seizures. Despite advances in pharmacological treatment, ~30% of people with epilepsy have poorly controlled seizures which increase mortality and the presentation of co-morbidities. Marijuana has historically been used to treat a wide variety of diseases including epilepsy but the psychoactivity of Δ9-THC prevents widespread acceptance of medical marijuana. Cannabidivarin (CBDV) and cannabidiol (CBD) are non-psychoactive phytocannabinoids (pCBs) present in marijuana that exert significant anticonvulsant effects in acute, in vivo models of seizure.

Here, we investigated the effects of a marijuana-derived botanical drug substance (BDS) principally containing CBDV and CBD and with Δ9-THC removed in the rat pentylenetetrazole (PTZ) and DBA/2 mouse audiogenic models of acute, generalised seizure. Furthermore, an isobolographic study design was employed to determine whether the anticonvulsant effects of CBDV and CBD interacted in any way.

Animals were group housed in a 12/12 hour light/dark cycle (21°C), with food and water provided ad libitum. Animals received i.p. BDS/pCBs one hour prior to convulsant stimulus. The seizure behaviour of male Wistar rats (24-28 days old) was assessed for 30 minutes following i.p. administration of PTZ (85 mg/kg). Male DBA/2 mice (21-28 days old) were placed in a bell jar, where a bell was sounded (110-120 dB) for ≤60 seconds to induce seizures.

In the PTZ model, the BDS significantly reduced seizure severity from a seizure that was fatal in 46% of cases to a severity that caused no mortality (175 mg/kg; n=15); an effect comparable to that exerted by matched levels of co-administered isolated CBDV and CBD. In the audiogenic model, the BDS significantly reduced the incidence of wild running and clonic convulsions (≥50 mg/kg; n=10). Using isobolographic experimental design and analysis, CBDV and CBD were found to interact in a linearly additive manner to suppress audiogenic seizures.

In conclusion, a BDS containing CBDV and CBD is strongly anticonvulsant and suppresses generalised seizures with similar potency to pure CBDV and CBD when co-administered; actions independent of the presence of Δ9-THC. Furthermore CBD and CBDV's anticonvulsant actions are linearly additive when administered in combination. These results strongly support wider clinical investigation of these non-psychoactive cannabinoids in epilepsy.

Title: Anticonvulsant effect of phenytoin transported by magnetic nanoparticles in an animal model of P-glycoprotein brain overexpression

Authors: *A. ROSILLO-DE LA TORRE[1], L. ZURITA-OLVERA[2], J. LUNA-BARCENAS[2], S. OROZCO-SUAREZ[3], P. GARCIA[4], L. ROCHA[1];
[1]Cinvestav, Distrito Federal, Mexico; [2]Cinvestav, Queretaro, Mexico; [3]IMSS, Mexico City, Mexico; [4]Univ. Autónoma de Ciudad Juarez, Chihuahua, Mexico

Abstract: Magnetic nanoparticles (MnPs) represent a potential and novel strategy to control pharmacoresistant disorders in which the brain overexpression of P-glycoprotein (P-gp) limits the achievement of effective therapeutic concentrations of drugs. The main goal of the present study was to evaluate the effects of phenytoin (PHT) loaded in the silica core of MnPs in an animal model of brain P-gp overexpression. MnPs were synthesized by coprecipitation and then covered with silica by the sol-gel method. PHT was loaded on the silica core shell by absorption with a final concentration of 62 mg/100 mg of MnPs. P-gp brain overexpression was induced in male Wistar rats by repeated seizure induction as consequence of 3-mercaptopropionic acid (3MP) (37.5 mg/kg i.p.) applied every 12 h for 11 administrations. MnPs-3MP group (n=10) received an administration of PHT loaded in MnPs (75 mg/kg, i.p.) one hour before the last 3MP injection. Results were compared with those obtained from the following groups:a) PHT-3MP group (n=9) in which the rats were manipulated as MnPs-3MP group, but injected with PHT (75 mg/kg i.p.) not loaded in MnPs; b) 3MP group (n=7) that only received repetitive 3MP administration. Latency and incidence to mioclonus, clonic and tonic-clonic seizures were assessed during 30 min immediately after 3MP injection. Animals were sacrificed 24 h after the last 3MP or saline administration, and their brain was used to evaluate the *P-gp expression by immunochemistry. During the last 3MP administration, rats from the 3MP group showed the following seizure latency and incidence: mioclonus at 4.5±2min (100%); clonus at 7.2±1.3 min (86%); tonic-clonic at 7.4±1.35 min (71%).* PHT-3MP group presented similar incidence for mioclonus (89%), clonus (89%) and tonic-clonic seizures (78%), *when compared with 3MP group. Concerning* MnPs-3MP group, animals presented similar incidence for mioclonus (70%), but reduced number of animals showed *clonus (40% $p<0.05$) and tonic-clonic events (20%, $p<0.02$). In contrast with 3MP group, PHT-3MP and MnPs-3MP groups showed similar latencies for the different type of seizures.*Immunohistochemical analysis revealed that the repeated administration of 3MP induced the overexpression of P-gp in blood brain vessels of different brain areas. The results of the present study support the idea that MnPs can be used as a therapeutic strategy to transport antiepileptic drugs to the brain of animals with P-gp overexpression. Future studies should be focused to evaluate the beneficial and undesirable effects of MnPs in experimental models of pharmacoresistant epilepsy.

Title: Liposome-encapsulated melatonin attenuates trimethyltin-induced neurotoxicity via inhibition of protein kinase Cδ proteolysis

Authors: *M.-B. WIE[1], J. LEE[2], Y. NAM[3], J. JEONG[3], J. LEE[4], E.-J. SHIN[2], H.-C. KIM[2]; [1]Col. of Vet. Med. and Inst. of Animal Med., [2]Neuropsychopharm. & Toxicology Program, Col. of Pharm., Kangwon Natl. Univ., Chunchon, Korea, Republic of; [3]Dept. of Pharmacology, Col. of Med., [4]Col. of Pharm., Chung-Ang Univ., Seoul, Korea, Republic of

Abstract: In the present study, we examined the effect of liposome-encapsulated melatonin (LM), a potent antioxidant, on the trimethyltin (TMT)-induced neurotoxicity. Male C57BL/6 mice received LM (20 mg/kg as a melatonin) subcutaneously twice a day from 7 days before TMT (2.8 mg/kg, i,p.) injection. Additional LM was injected until 2 days after TMT. Convulsive behavior was measured at 1 and 2 days after TMT injection, and then mice were sacrificed for histological observation. Treatment with LM significantly attenuated TMT-induced convulsive behavior. Consistently, TMT-induced nuclear chromatin clumping was also significantly decreased by LM in the dentate gyrus of hippocampus. Since we and others have suggested that PKCδ plays an important role on the oxidative damage in various neurotoxic conditions, we then examined whether treatment with LM modulates the expression of PKCδ and its cleaved form after TMT injection. Hippocampal expression of cleaved-PKCδ was significantly increased in the TMT-treated mice as compared with saline-treated mice, and these changes were significantly attenuated by treatment with LM. Our results suggest for the first time that inhibition of PKCδ proteolysis mediated by LM provides a potential neurotherapeutic intervention in response to TMT-induced excitotoxicity.

Title: Anticonvulsant action of the cyclooxygenase inhibitor celecoxib in an *In vitro* post-traumatic epilepsy model

Authors: *K.-I. PARK, Y. SAPONJIAN, V. DZHALA, M. MAIL, K. STALEY;
Neurol., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Celecoxib, a cyclooxygenase 2 inhibitor, has been studied as a possible anticonvulsant in numerous experimental paradigms. However, its efficacy as an anticonvulsant is still controversial. We screened a large number of compounds for anticonvulsant activity using the hippocampal organotypic slice preparation as a model of post-traumatic epileptogenesis (Berdichevsky et al. *J Neurosci* 2013). Celecoxib proved to be efficacious in the screening protocol, so we tested 1) whether the efficacy of celecoxib (10μM) was evident electrophysiologically in the slice cultures, 2) whether it altered the acute seizure activity induced by low-Mg perfusion of intact hippocampal formations and 3) whether celecoxib exhibited antiepileptogenic effects. Extracellular field potential recordings confirmed the anticonvulsant efficacy celecoxib in the organotypic slice culture model of posttraumatic epilepsy: reductions of the power of epileptic activity were 62.8% ($p<0.01$) in early stages of epilepsy and 56.9%, ($p<0.01$) in later stages. Seizure frequency decreased by 81.5% ($p=0.02$) and 67.5% in early and later stage respectively. However, celecoxib was not effective against seizure activity induced acutely in normal tissue. Celecoxib applied to slice cultures for 3 weeks followed by a 4-day washout did not prevent or alter the emergence of seizure activity, indicating that celecoxib does not exhibit antiepileptic activity in this preparation. Spontaneous seizures were observed in 44% of slices in celecoxib group and 67% in control group after washout. Total duration of seizures was longer (54.8±4.6 min vs., 18.3±3.1 min, $p<0.01$) and the number of microglia was higher 282.2±25.1/mm^2 vs., 198.9±13.4/mm^2 $p=0.03$) in celecoxib group. Astrogliosis was not significantly different. In conclusion, our data provide evidence of an acute anticonvulsant effect of celecoxib in models of chronic post-traumatic epilepsy, but not in acute seizure models based on normal brain tissue. The robust anticonvulsant effects of celecoxib in this in vitro post-traumatic model underscores the potential of cyclooxygenase as a target of chronic epilepsy treatment. The modest effects of celecoxib in acute seizure models highlights the utility of the organotypic slice culture model as a complimentary screen for drugs to treat epilepsy that does not respond to currently-available agents discovered using acute seizure models.

Title: Synthetic Vitamin K derivatives provide protection in multiple neurological disease models

Authors: *B. JOSEY, R. COMER, E. INKS, J. RAHN, S. CHAN, J. CHOU;
Med. Univ. of South Carolina, Charleston, SC

Abstract: For the past century, vitamin K has been known to be an essential cofactor for the γ-carboxylase activity, which is involved in blood coagulation and calcium-binding protein in bone formation. Recently, vitamin K has begun to emerge as playing a critical role in brain function, although much about its physiology in the brain remains unknown. Vitamin K has two major forms: vitamin K1 and vitamin K2. Vitamin K1, phylloquinone, is synthesized in green leafy vegetables because of its role in photosynthesis. Vitamin K2, menaquinone, is the predominant and biologically relevant form in animals and has several subtypes depending on the number of side chain isoprenoid residues. One of these subtypes, MK-4, is the dominant form of vitamin K found in human tissues, and recent studies indicate that MK-4 constitutes 98% of vitamin K found in brain tissue and is highly concentrated in the midbrain and pons medulla. Most forms of vitamin K have relatively poor bioavailability, and it is hypothesized that MK-4 is likely endogenously synthesized in situ from dietary phylloquinone, via side chain cleavage, transport, and site selective prenylation to produce tissue-specific menaquinones. The capacity to convert both pylloquinone and menadione to MK-4 by cultured brain slices has been demonstrated, further implicating an important role of the nutrient in brain physiology. Results from recent studies indicate that brain levels of VK decrease with age and that decreased VK levels correlate with cognitive decline in neurodegenerative diseases, although to date very little research has gone into characterizing the extent of its impact. The cause of this decrease is still unknown, although it is likely due to some defect in the absorption of the lipophillic molecule, the transport mechanisms involved with getting it to the brain, or in the biosynthetic machinery. These data indicate that the development of small drug-like substitutes of vitamin K that are biologically stable and capable of penetrating the blood brain barrier could be potentially valuable. We have previously reported a structure-activity relationship study of vitamin K that yielded several small molecule analogs that protected neuronal cultures from various forms of cell death. Herein, we present the characterization of synthetic VK derivatives with no observable toxicity in vivo that

demonstrate improved bioavailability and brain tissue uptake. These derivatives provide protection in multiple in vitro and in vivo models of neurological disorders, including the prevention of seizures in the murine 6 Hz corneal stimulation model, indicating potential use in the treatment of therapy-resistant epilepsy.

Title: Resveratrol treatment after the onset of status epilepticus reduces neurodegeneration and inflammation in the adult hippocampus

Authors: *V. MISHRA[1,2], B. SHUAI[1,2], B. HATTIANGADY[1,2], A. K. SHETTY[1,2];
[1]Inst. for Regenerative Med., Texas A&M Hlth. Sci. Ctr. Col. of Med., Temple, TX; [2]Central Texas Veterans Hlth. Care Syst., Temple, TX

Abstract: Status epilepticus (SE) is a life-threatening emergency medical condition, typified by prolonged seizure activity. Currently available medications for SE such as antiepileptic drugs (AEDs) suppress seizures in most patients but do not prevent seizure-induced neurodegeneration. Furthermore, AEDs fail to modify the down-stream detrimental effects of SE such as neuroinflammation and chronic epilepsy development. Thus, efficient neuroprotective and antiepileptogenic strategies are needed for preventing SE-induced morbidity. In this study, we rigorously examined the efficacy of resveratrol (RESV), a phytoalexin found in the skin of red grapes having potent antioxidant and anti-inflammatory properties, for preventing SE-induced neurodegeneration and neuroinflammation in the hippocampus. Graded intraperitoneal injections of kainic acid (3 mg Kg bw/hour for 3-4 hours) were employed to induce SE in young adult F344 rats. Groups of rats exhibiting SE received either intraperitoneal RESV (30 mg/Kg, commencing an hour after the induction of SE and continuing every hour for 3 hours on SE induction day and twice daily thereafter for 6 days) or vehicle (VEH). Behavioral seizures were terminated in both RESV and VEH treated animals at 2 hours after the induction of SE with an injection of

diazepam (5 mg/Kg). Stereological counting of neurons expressing the neuron-specific nuclear antigen (NeuN) at 7 days post-SE revealed considerable loss of neurons in the hippocampus of rats receiving VEH after SE, in comparison to the naïve control group (64% in the dentate hilus, 19% in the granule cell layer, 40-53% in CA1 and CA3 pyramidal cell layers; $p<0.01$). Contrastingly, in rats receiving RESV after SE, these populations of neurons were largely preserved. Furthermore, RESV-treated rats displayed reduced numbers of ED-1+ activated microglia than VEH-treated rats in the CA1 and CA3 subfields (33-55% reduction, $p<0.01$), implying repression of inflammation by RESV. Additionally, RESV treated rats exhibited survival of greater numbers of GABA-ergic interneurons expressing neuropeptide Y (NPY) and parvalbumin (PV) than VEH treated rats ($p<0.05$), suggesting protection of interneurons by RESV. Thus, RESV treatment after the onset of SE is efficacious for protecting principal as well as GABA-ergic neurons, and reducing neuroinflammation in the hippocampus. As loss of GABA-ergic interneurons and neuroinflammation are believed to contribute greatly towards the evolution of initial SE-induced hippocampal injury into chronic epilepsy, RESV treatment after SE may be beneficial for restraining SE-induced chronic epilepsy and other co-morbidities.

Title: Delayed post-treatment with atropine sulfate arrests generalized seizures induced by soman in immature male rats

Authors: *S. L. MILLER[1], T. H. FIGUEIREDO[1], E. M. PRAGER[1], C. P. ALMEIDA-SUHETT[1], J. P. APLAND[2], V. ARONIADOU-ANDERJASKA[1], M. F. M. BRAGA[1]; [1]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [2]United States Army Med. Res. Inst. of Chem. Def., Edgewood, MD

Abstract: Nerve agents irreversibly inhibit the enzyme acetylcholinesterase (AChE) in the peripheral and central nervous system. Following nerve agent intoxication prolonged seizures result from the hyperstimulation of muscarinic acetylcholine receptors (mAChRs) within the

basolateral amygdala (BLA). Experimental models suggest children would be highly susceptible to seizures and death following nerve agent exposure. Asoxime chloride, an oxime, and atropine sulfate (ATS), a general muscarinic antagonist, are considered the standard of care for nerve agent intoxication in adults. However, it is unknown if these drugs will be an effective delayed treatment in children. Knowledge of the effects of nerve agents on immature animals is limited. We determined the median lethal dose (1 X LD50) of soman on P21 male rats to be 62 μg/kg, which is less than 2/3 of the dose for adult male rats. We tested whether immature male rats are more sensitive to soman due to reduced AChE activity in the BLA. We found a significant reduction in AChE activity in the BLA following soman induced seizures, whereas AChE activity was reduced in the prefrontal cortex, piriform cortex and hippocampus in animals without seizures. We exmained whether differences in mAChR subtype expression within the BLA may explain the sensitivity of immature rats to soman. mAChR expression in the mouse BLA was semi-quantitatively analyzed using publically available in situ hybridization data from the Allen Institute for Brain Science. A developmental reduction in M2 mAChRs-which open potassium channels-was found and may contribute to soman sensitivity. Due to incomplete expression of all mAChR subtypes, we hypothesized a low dose of ATS would counteract soman induced seizures. We administered 2.0 mg/kg ATS 20 minutes post exposure to soman (1.2 X LD50). This dose arrested generalized seizures in 100% of treated animals. These data may explain the sensitivity of immature male rats to soman and the potent efficacy of ATS against soman induced seizures.

Title: Biosimulation of mesiotemporal lobe epilepsy for the search of new antiepileptic drugs and anticipation of proconvulsant risks

Authors: A. LEGENDRE[1], F. PERNOT[1], R. GREGET[1], C. ROUCARD[2], A. DEPAULIS[3], L. FAGNI[4], A. F. KELLER[1], N. AMBERT[1], M. SARMIS[1], *J.-M. C. BOUTEILLER[5,1], M. BAUDRY[1,6], T. W. BERGER[5,1], S. BISCHOFF[1];

Abstract: Mesiotemporal lobe epilepsy (MTLE) is the most common form of human epilepsy, it is characterized by focal seizures, typically associated with hippocampal sclerosis (Langlois et. al. 2010). Prior to surgical intervention, physicians empirically seek a drug combination to abolish seizures. Unfortunately, MTLE is often resistant to conventional treatments, and great efforts have been made to discover new antiepileptic drugs (AEDs), with very limited success. In this study, we used a biosimulation approach to bring new insights on the roles of different molecular mechanisms that control the excitatory/inhibitory balance in hippocampus. We first developed kinetic models of a large number of receptors and transporters and assessed the effects of several AEDs (CGP-40116, Picrotoxine, Muscimol, Gabazine, Tiagabine, Carbamazepine, Lamotrigine) on these elementary models. These elementary blocks were then integrated into models of glutamatergic and gabaergic synapses, which were incorporated into a model of a CA1 pyramidal neuron (Jarsky 2005). Finally, we implemented the microcircuitry that surrounds CA1 neurons to take into account feedforward inhibition to the perisomatic area through basket cells, and feedback inhibition driven by O-LM interneurons. All elementary models were developed and validated using RHENOMS (V2) modeling and simulation platform, and then integrated to the NEURON Simulation environment (Hines 1997). The model reproduced epileptiform activities (paroxysmal depolarization shift or PDS), as well as dose-dependent responses to AEDs, in good agreement with results observed in an in vitro model of epilepsy (low magnesium concentration) and In vivo (kainate mouse model). The model was then used to analyze the effects of combinations of various doses of AEDs to detect possible synergetic or asynergetic effects. The approach illustrates the value of the multiscale simulation platform for the study of epilepsy and for the discovery of novel therapeutic agents. It allows addressing fundamental as well as translational questions, and provides a strong support for drug research and discovery, especially for the development of complex therapeutic strategies or the assessment of toxicity risks.

Title: The behavioral rescue with rapamycin early following status epilepticus is not long-lasting

Authors: *A. CARTER[1,3], A. L. BREWSTER[2], J. N. LUGO[2], W. L. LEE[2], A. E. ANDERSON[2];
[2]Pediatrics, [1]Baylor Col. of Med., Houston, TX; [3]Dept. of Neurosci., Houston, TX

Abstract: RATIONALE: Status epilepticus (SE) is associated with the development of epilepsy and comorbidities, including deficits in cognition. Previous studies have implicated the mammalian target of rapamycin (mTOR) signaling cascade in the pathophysiology of SE and epilepsy using the mTOR complex 1 (mTORC1) inhibitor rapamycin (Rap). Under basal conditions, mTORC1 regulates protein synthesis and is an important mediator of synaptic plasticity. We have recently shown that aberrant mTOR signaling contributes to behavioral deficits that occur 2 weeks following SE. In the studies reported here, we determined whether aberrant mTORC1 signaling plays a role in hippocampal-dependent learning and memory tasks, locomotion, and anxiety in the epileptic animal and whether early rapamycin rescue is long-lasting.
Methods: SE was induced in rats using pilocarpine (SE) while controls (Sham) received saline. Two weeks after SE induction, we administered Rap or vehicle (Veh) every other day for one week. The treatment groups were Sham+Veh, Sham+Rap, SE+Veh, and SE+Rap (n=7-12 per group). We tested SE and Sham animals (from each treatment group) in the Morris Water maze (MWM), Novel Object Recognition (NOR), and the Open Field task (OF) tasks. To determine whether early Rap was long lasting, we tested animals 5 months after treatment (n=6 per group). After behavioral testing was completed, we performed western blotting to verify inhibition of mTORC1 (S6 phosphorylated at S240/244).
Results: SE+Veh rats exhibited significantly longer escape latencies during the acquisition phase in MWM test and decreased time spent in the target quadrant searching for a hidden platform compared to Sham+Veh animals ($p< 0.05$ and $p<0.01$, respectively). In NOR, SE+Veh animals displayed no preference for the novel object as compared to controls ($p<0.001$). In the SE+Rap group, the deficits in MWM and NOR were rescued to performance levels of Sham+Veh animals. SE+Veh rats spent more time in the inner portion of the OF arena than Sham + Veh and

displayed increased distance traveled and travel velocity ($p<0.05$). When tested 5 months after SE, early Rap treatment did not attenuate any hyperactive locomotion in OF nor did early Rap treatment rescue any deficits in MWM or NOR (p-values not significant). For all behavioral tasks, Rap had no effect on Sham + Rap animals.
Conclusions: These data suggest that aberrant mTORC1 signaling contributes to deficits in hippocampal-dependent learning and memory. Future studies are planned to evaluate whether late mTORC1 inhibition may rescue these deficits in animals in which epilepsy has already been established, particularly since the early treatment is not long lasting.

Title: Anticonvulsant activity of a parenteral allopregnanolone formulation in mouse seizure and status epilepticus models

Authors: *D. ZOLKOWSKA[1], A. DHIR[1], C. WU[1], H. WULFF[2], B. INCEOGLU[3], B. D. HAMMOCK[3], P. J. LEIN[4], M. A. ROGAWSKI[1];

Abstract: Allopregnanolone (3α-hydroxy-5α-pregnan-20-one; 5α,3α-P) is an endogenous progesterone-derived neuroactive steroid that is positive allosteric modulator of synaptic and extrasynaptic GABAA receptors. 5α,3α-P exerts anticonvulsant activity in diverse animal seizure models, including models of status epilepticus (SE). SE is a neurological emergency requiring rapid treatment, typically by the IV (intravenous) or IM (intramuscular) routes. Here we characterized the activity of a parenteral 5α,3α-P formulation in the 6 Hz and PTZ seizure models, and in a new SE model. 5α,3α-P was formulated in 6% (0.5 and 1.5 mg/ml) and 24% (6 mg/ml) sulfobutylethers β-cyclodextrin sodium salts (Captisol®) in 0.9% saline. 5α,3α-P was injected IV or IM in mice prior to administration of a 6 Hz electrical stimulus or PTZ (80 mg/kg, IP). In the 6 Hz seizure model, 5α,3α-P in doses of 0.5 and 1.5 mg/kg IV conferred seizure

protection in 50% and 100% of animals at 1 min after dosing. The protective effect declined rapidly and was no longer evident at 15 and 30 min after the IV bolus with the low and higher doses, respectively. 5α,3α-P IV at doses as low as 0.25 mg/kg significantly delayed the onset of PTZ-induced seizures. 5α,3α-P IM was similarly effective in the 6 Hz model: 1.5, 3 and 6 mg/kg doses protected 50%, 90% and 100% of animals, respectively. Seizure protection peaked at 5-10 min and persisted for up to 60 min. 5α,3α-P IM at doses as low as 0.5 mg/kg significantly delayed the onset of PTZ-induced seizures in mice. SE was induced with tetramethylenedisulfotetramine (TETS; 0.2 mg/kg IP) followed by riluzole (10 mg/kg IP). After 30 min of SE, mice were treated IM with 5α,3α-P or vehicle and observed for 1 h. All surviving animals were checked daily for 7 days. 5α,3α-P IM at dose of 3, 6 and 12 mg/kg terminated SE within 1 h and prevented mortality in 67%, 67% and 83% of animals, respectively. In conventional mouse seizure models, 5α,3α-P is highly potent when administered IV but it has a short duration of action; the onset of action is modestly delayed and the duration of action is prolonged with IM administration. 5α,3α-P is also effective in terminating seizures and maintaining survival following persistent seizure activity. These studies support the potential of 5α,3α-P in the treatment of SE.

Title: Characterization of methamphetamine’s effect on post-traumatic epilepsy

Authors: D. SMITH, D. BROOKS, E. WOHLGENHAGEN, T. RAU, *D. J. POULSEN; Dept Biomed & Pharmaceut. Sci., Univ. Montana, MISSOULA, MT

Abstract: We have shown that low-dose methamphetamine significantly improves cognitive and behavioral outcomes following severe TBI. We hypothesized that methamphetamine might also protect against post-traumatic seizures. In this study, we used the well-established and clinically relevant rat lateral fluid percussion injury model to induce severe TBI. At 36 hours after injury, cortical tissue from controls and methamphetamine treated groups were analyzed via gene array. Interestingly, methamphetamine significantly altered the expression of several genes previously

implicated in seizure activity, including those involved in neuroinflammation and blood-brain-barrier integrity. These data support the concept that methamphetamine may prevent or reduce post-traumatic seizures.
We conducted immunohistochemical analysis to further examine the potential of methamphetamine to reduce post-traumatic seizures. TBI causes the loss of parvalbumin and somatostatin positive inhibitory interneurons. We have observed a significant loss of parvalbumin and somatostatin positive cells within the cortex and hippocampus at 46 days following severe TBI. We have also observed a significant loss of the glutamate transporter, EAAT2 within the cortex and hippocampus at 46 days pot injury. This loss of inhibition and enhanced excitatory signal potential can promote seizure activity. Methamphetamine treatment does not appear to preserve inhibitory interneurons nor prevent the loss of EAAT2. We are currently conducting additional analysis to investigate other seizure-associated proteins identified by gene array.
Video/EEG recordings were also captured to characterize epileptiform wave patterns and clinical seizure behavior following severe TBI. Preliminary results indicate an evolution of epileptic activity following TBI characterized principally by interictal spikes, and myoclonic seizures. Our preliminary results suggest that methamphetamine does not alter spontaneous seizure development within 2 months of injury. Additional experiments, which incorporate a PTZ challenge, are underway to determine if methamphetamine treatment alters seizure susceptibility. Data from these studies will help to identify critical changes that occur after TBI and focus efforts on those that make significant contribution to post-traumatic epilepsy.

Title: Epilepsy and consciousness: Behavioral deficits in partial seizures are bimodally distributed

Authors: *C. CUNNINGHAM[1], W. CHEN[1], A. SHORTEN[1], T. CHOEZOM[1], M. MCCLURKIN[1], C. SCHMIDT[1], A. BOZIK[1], C. BEST[1], M. CHAPMAN[1], V. CHU[1], M.

FURMAN[1], J. T. GIACINO[2], H. BLUMENFELD[1];
[1]Yale Sch. of Med., New Haven, CT; [2]Harvard Med. Sch., Boston, MA

Abstract: Impaired consciousness in epilepsy has a significant negative impact on patient quality of life, yet the mechanisms for loss of consciousness during seizures are poorly understood. In this study, we explore whether impaired consciousness during partial seizures can usually be attributed to specific deficits in the content of consciousness or to a more general decrease in the overall level of consciousness. Prior studies concerning loss of consciousness during seizures have relied on retrospective and subjective methods. We recently developed the responsiveness in epilepsy scale (RES), a prospective tool for assessing ictal behavior that provides objective data about specific deficits in cognition and sensorimotor function. Here we examine the results of RES testing in 83 partial seizures captured in 30 patients. All patients were recruited during admission to Yale New Haven Hospital, and were undergoing continuous video/EEG (cVEEG) for seizure evaluation at the time of enrollment. All seizures were scored on a scale from 0 to 4, and performance for partial seizures were analyzed based on the initial cycle of ictal testing. We find that RES scores tend to be bimodally distributed, such that scores of 0 (no response) and 4 (unimpaired response) occur most frequently for all RES items. Furthermore, 75 of 83 partial seizures tested receive a score of 0 or 4 on the first RES question administered, and this initial performance predicts impairment on subsequent items. These distinct patterns of impairment correlate with those seen in “simple partial” and “complex partial” seizures. To determine whether the bimodal distribution of RES scores might be related to bias intrinsic to the scale, we also examined results of standardized testing in a cohort of brain-injured patients. In this comparison group, responsiveness was assessed using the JFK Coma Recovery Scale_Revised (CRS-R), a validated tool for assessing the minimally conscious state from which the RES was derived. We analyze the score distributions for the CRS-R subscales used to derive most RES items, and compare these results to RES scores in partial seizures. We find that scores in brain-injured patients are not bimodal, and are more evenly distributed than in partial seizure patients, suggesting that the bimodal nature of RES scores is not a result of scale bias but may be a finding unique to partial seizures. Our results indicate that partial seizures can often be cleanly separated into those with vs. without overall impaired responsiveness. These findings suggest that impaired level of consciousness affecting overall behavioral arousal in partial seizures may be crucial rather than selective deficits.

Title: Spatiotemporal evolution of seizures using a 3D object detection algorithm

Authors: *R. WAHNOUN, A. BHARGAVA, P. D. ADELSON;
Barrow Neurolog. Inst. At Phoenix Childrens Hosp., Phoenix, AZ

Abstract: Approximately 65 million people worldwide are living with epilepsy. While some cases can be controlled with anti-epileptic drugs, others require more drastic measures for alleviation. In these situations, focal resection surgery may be considered. Prior to surgery, patients must undergo a battery of tests, including electrocorticography (ECoG) under which electrodes arrays are placed on the surface of the brain for a period of 1-3 weeks. Seizures onsets are located by visually assessing pattern changes in the brain signals.
This study aims to elucidate novel information regarding seizure origin and spread from a quantitative perspective, using a combination of signal and image processing techniques on ECoG data.
It is hypothesized that the spatiotemporal spread of seizures contains information that may be useful in focal resection surgery and offers a clinical advantage over subjective expert estimation. Refining ictal localization could minimize brain tissue removal, and eventually reduce function loss.
Raw cortical data are transformed in the spectral domain, and then converted into sequences of images. These “videos” of cortical signals are then processed through an object detection algorithm to estimate and locate bursts of activity.

Title: Human mesial temporal lobe single neuron dynamics during recruitment into a generalizing seizure

Authors: *A. MISRA[1], X. LONG[1], M. SPERLING[2], A. SHARAN[3], K. MOXON[1]; [1]BIOMED, Drexel Univ. BIOMED, Philadelphia, PA; [2]Neurol., [3]Neurolog. Surgery, Thomas Jefferson Univ., Philadelphia, PA

Abstract: The seizures of temporal lobe epilepsy, which are associated with an increased resistance to pharmacotherapy, can be roughly classified as generalizing, (in our case spreading from neocortex to limbic structures), and non-generalizing. Recent studies of single neuron activity have found heterogeneity of the activity of neocortical neurons prior to the onset of seizures. However, animal studies in limbic structures, including those from our own lab focusing putative pyramidal cells and interneurons, demonstrate that these two populations may have distinct firing patterns. To identify similar patterns in humans, platinum-iridium micro-wires were implanted into the mesial temporal lobe of patients undergoing diagnostic evaluation at Thomas Jefferson University under approval of the university institutional review board and according to OHRP guidelines. Patients were continuously recorded (24/7) using a high-speed acquisition system (0.8Hz - 9000 Hz) (Neuralynx, Bozeman MT). Data from 9 generalizing and 9 non-generalizing seizures across 8 patients were analyzed. 105 single neurons were discriminated (Offline Sorter, Plexon, Dallas TX) during preictal periods (two hours terminating in seizure onset) and 44 during interictal periods (more than 12 hours from seizure onset). Population peri-event time histograms were created by aligning each seizure to its onset time as determined clinically, binning the data into 2 second bins and averaging the firing rate in each bin for all neurons across all seizures. In a similar manner, normalized unit-field coherence spectrograms were created. For non-generalizing seizures there were no changes in firing rate or unit-coherence for either pyramidal cells or interneurons. For generalizing seizures, pyramidal cell activity increased within seconds of seizure onset with no measurable change in unit-field coherence. Interneurons, on average, showed a significant decrease in firing rate starting approximately 1 minute prior to seizure onset. Moreover, similar to our data from animal studies, there was an average decrease in unit-field coherence from 1-8 Hz in the 10 minutes prior to seizure. On a per-neuron level this pattern of activity was present in 50% of recorded interneurons across 75% of generalizing seizures. These data suggest that seizure spread through white matter tracts, similar to seizure spread within cortical structures, may depend on a break-down of inhibition in recruited structures.

Title: Spatial variability of cortical ripples in humans

Authors: *E. TÓTH[1,2], L. ENTZ[3], I. ULBERT[2,1], L. ERőSS[3,1], D. FABÓ[3];
[1]Pázmány Péter Catholic Univ., Budapest, Hungary; [2]Res. Ctr. for Natural Sci. Inst. of Cognitive Neurosci. and Psychology, Hungarian Acad. of Sci., Budapest, Hungary; [3]Natl. Inst. of Neurosciences, Budapest, Hungary

Abstract: Background
Based on animal and human research ripple oscillations (80-300Hz) participate in physiological processes and epileptiform transformations in the brain. The cortical generators of such fast oscillations were demonstrated to have generators limited to a small cortical area. The purpose of this study is to describe the spatial variability of ripple oscillations and demonstrate that wide cortical area can contribute to their generation.
Methods
Epilepsy patients undergoing invasive preoperative evaluation were selected in this study. Two patients had focal cortical dysplasia in the right postcentral gyrus, and had therapy resistant elementary motor seizures. The central area was covered by subdural grid electrodes. Ripple oscillations were detected on slow wave sleep EEG segments using semi automated method, first detecting putative ripple events (PR) exceeding 5 standard deviation (SD) of band pass and root mean square filtered data, and thereafter visual selection was performed.
Results
The majority of PRs appeared on 1 or 2 channels, but there was a significant proportion of the events presented on various number of channels, in some cases almost all channels. Wide range ripples were found more often in the proximity of the seizures. In this case bimodal distribution was observed in the involved channel number histogram.

Discussion
We demonstrated that relatively large cortical areas may contribute to the genesis of ripple oscillations, that area might vary significantly. Two populations of small and wide range ripples were demonstrated. We hypothesize that the cortical extent of the ripples may be a factor of it's epileptogenic nature.

Title: Accurate estimation of cortico-cortical distance between intracranial electrode contacts

Authors: *J. D. TURNER[1], B. JOSHI[1], A. PANDAY[1], R. MUNBODH[2], H. P. ZAVERI[3]; [1]Electrical and Computer Engin., UNC Charlotte, Charlotte, NC; [2]Radiation Oncology, Univ. of Pennsylvania, Philadelphia, PA; [3]Neurol., Yale Univ., New Haven, CT

Abstract: Objective: Intracranial EEG (icEEG) inter-contact distance, which is important for measurements of brain relationship and estimates of time-delay, is commonly estimated as the Euclidian distance between the centers of two icEEG contacts. We propose a more accurate method to calculate the distance between icEEG contacts.
Methods: Intracranial EEG electrode contacts placed in 22 adult patients being monitored for epilepsy surgery were accurately located from post-implant CT and co-registered to a pre-implant MRI scan and the MRI of a standard brain. The MR images were rendered as a 3D surface. Cortico-cortical distances along the brain surface were calculated using a variant of Dijkstra's algorithm, a common shortest-path algorithm. The surface distance estimates were compared to the Euclidean distance.
Results: The surface distance estimates were significantly greater than the Euclidean estimates and can generally be approximated as being 30% longer. The largest discrepancy between surface and Euclidean distances was observed for distances between 4.5cm and 8cm. Difficulties resulted from inaccurate location of icEEG contacts on the brain surface, and previous resective surgery.
Discussion: A considerable difference between brain surface and Euclidean distances was observed. In its current form, the algorithm takes nearly 20 hours to complete analysis of a single patient, while Euclidean distances can be calculated in real time. Ongoing work involves

increasing the speed of the algorithm and addressing the challenges listed above.
Conclusions: The Euclidean distance metric can considerably underestimate the distance between two icEEG electrode contacts. This approximation can adversely affect estimates of brain relationship and time-delays. A more accurate distance measure is possible through the application of Dijkstra's algorithm to the brain surface rendered from the MRI of the patient brain.

Title: Immunolocalization of metallothionein in patients with temporal lobe epilepsy

Authors: *M. MENDEZ-ARMENTA[1], C. NAVA-RUIZ[1], M. ALONSO-VANEGAS[2], M. BUENTELLO-GARCÍA[2], D. JUAREZ-REBOLLAR[1];
[1]Dept Neuropathol, [2]Dept Neurosurg., Natl. Inst. Neurol Neurosurg., Mexico City, Mexico

Abstract:
Temporal lobe epilepsy (TLE) is the most prominent example of acquired and frequent epilepsy which is commonly preceded by an initial brain injury such as an episode of prolonged seizures or status epilepticus (SE), childhood febrile seizures, hypoxia or trauma and becomes pharmacologically untreatable in a high percentage of patients. Two main types of TLE are generally recognized, mesial temporal lobe epilepsy which arises in the hippocampus, parahippocampal gyrus and amygdala, and lateral temporal lobe epilepsy which arises in the neocortex. On the other hand, there are four isoforms of metallothionein (MT-I - IV), of which

MT-I and -II are the best characterized, in the central nervous system (CNS), MT-I+II are expressed coordinately and are increased in macrophages/microglia and astrocytes during various inflammatory and pathologic conditions including human neurodegenerative disorders, brain injury, oxidative stress, neurodegeneration, heavy metals, and epileptic seizures.The MTs occur in several brain regions and may serve as neuroprotective proteins against reactive oxygen species causing oxidative damage and stress, ionizing radiation, or anti-cancer drugs. The main aim of this work was to describe the immunohistochemical localization of MT in the specimens derived from the patients affected by MTLE. Samples were collected of patients with TLE, patients were submitted to the protocol set out by the Epilepsy Surgery Program of the INNN in Mexico, which comprises an extensive pre-surgical clinical evaluation, video-electroencephalogram (EEG) record, magnetic resonance maging (MRI) and single photon emission computed tomography (SPECT). NeuN, GFAP, and MT antibodies were used for immunohistochemical analysis. Histopathological examination showed NeuN immunopositive cells that were analyzed for determinate the neuronal density in hippocampal and parietal cortex samples. Increased reactive astrogliosis in CA2 and CA3 of hippocampus was observed and increase MT immunoreactivity was also observed in cell and nueropil of TLE samples. In conclusion, an increased in MT expression was observed in samples from TLE patients, this is important due to MTresponse in brain damage associated to seizures and these results suggest that further studies are needed to investigate the possible neuroprotective role of MT on TLE.

Abstract: Objective: In this study we evaluated the expression of cytokines in patients with refractory temporal lobe epilepsy and cortical dysplasia.
Methods: We studied 13 patients (5 women and 8 men), 7 with refractory epilepsy and 6 different types of tumors with an average age of 30.6, with refractory temporal lobe epilepsy, All patients were studied by preoperative protocol standardization and temporal lobectomy candidates and amygdalohippocampectomy. The expression and distribution of TNF, IL-1β, IL-6 and COX were studied immunohistochemically in regions T1, T2, T3.
Results: We found disorganization of cortical architecture, neuronal loss, starch bodies, spongiosis, apoptotic cells, hypertrophic, dysplastic and dysmorphic neurons, ballon cells with atypical nuclei, cytoskeletal disruption in dense fibrillar aggregates, the cortical dysplasia 69.23% type IIA, and the 30.77% type IIB, numerous fibrillary astrocytes, were observed, the majority of patients have extensive cell death in the cortex, TNF-α, IL-1β, IL-6 were significantly increased in patients with epilepsy Conclusions: Our results suggest that these structural lesions and the inflammatory events will be casually associated, as well as also we found a relation with the type dysplasia, in these patients with refractory epilepsy, these findings support the idea that neuroinflammation is oriented to activation of the microglia and the astrocytes by reduce neurological morbidity and seizure control in these patients.

Title: Evaluation of the density and signaling of histamine H3 receptors in the temporal cortex and hippocampus of patients with pharmacoresistant temporal lobe epilepsy

Authors: *I. BAÑUELOS-CABRERA[1], M. CUELLAR-HERRERA[2], S. OROZCO-SUAREZ[3], M. ALONSO-VANEGAS[4], J. ARIAS-MONTAÑO[1], L. ROCHA[1];

Abstract: Temporal lobe epilepsy (TLE) is the most common type of epilepsy and becomes pharmacologically untreatable in a high percentage of patients. In TLE associated with mesial sclerosis (MTLE), the hippocampus is the epileptic focus, while the temporal cortex is involved in the propagation of epileptic seizures to other brain areas. Epilepsy involves changes in several neurotransmitters. Concerning the histaminergic system, several studies in seizure and epilepsy models suggest that histamine may exert anti- or pro-convulsant effects, the latter presumably mediated by the H3 receptor. The present study was carried out to determine the density and signaling of H3 receptors in the hippocampus and temporal cortex of 10 patients with pharmacoresistant MTLE. Tissue samples were obtained immediately after surgical resection. Results were compared with those obtained from 6 autopsies. Cell membranes were obtained from tissue samples by homogenization and centrifugation and used to determine the binding of N-α-[methyl-3H] histamine ([3H]-NMHA), a selective H3 receptor agonist. Activation of G proteins subsequent to stimulation of H3 receptors by the selective agonist immepip was also investigated by [35S]-GTPγS binding assay. For this assay, values of maximal stimulation (Emax) and half-effective concentration (EC50) were determined by non-linear regression (GraphPad Prism 5.0). Protein contents were determined according to the method of Lowry. The values of specific [3H]-NMHA binding, Emax and basal [35S]-GTPγS binding obtained from patients with MTLE were expressed as the percentage change with respect to the values obtained from autopsies. Specific [3H]-NMHA binding showed no significant changes in density of H3 receptors in the hippocampus (51%, $p>0.05$) and temporal cortex (28%, $p>0.05$) of patients with MTLE. In the hippocampus of patients with MTLE, the [35S]-GTPγS binding assay revealed no changes in the values of Emax (28%, $p>0.05$) and EC50 (from 2.2 to 1 nM, $p>0.05$). The temporal cortex of patients with MTLE demonstrated no changes in EC50 (from 1.3 to 1.5 nM, $p>0.05$), but increased Emax values (121%, $p<0.01$), an effect probably associated to high basal [35S]-GTPγS binding (177%, $p<0.05$). Our present data provide evidence that in the temporal

cortex of patients with pharmacoresistant MTLE there is an alteration in the signaling of the H3 receptor.

Title: Co-localized measurements of intracranial EEG spikes and extracellular glutamate in patients with medically intractable epilepsy

Authors: N. GANESH[1], C. ONG[2], C. HALDEMAN[2], E. DAMISAH[3], I. I. GONCHAROVA[1], D. D. SPENCER[3], T. EID[2], *H. ZAVERI[1];
[1]Neurol., [2]Lab. Med., [3]Neurosurg., Yale Univ., New Haven, CT

Abstract: Purpose: Interictal spikes are considered to be a marker of excitability in the epileptic brain, though recent work by us and others has questioned whether spikes more truly reflect inhibition rather than excitation. We have also reported that basal levels of extracellular glutamate are increased in the epileptic brain. Here we sought to correlate co-localized measurements of interictal spikes and basal extracellular glutamate concentrations in patients undergoing intracranial EEG (icEEG) monitoring for epilepsy surgery.
Methods: A total of 20 patients were included in this study. Brain microdialysis measurements of glutamate and glutamine obtained from 59 combined depth EEG electrode/microdialysis catheters (Spencer probes) were analyzed. Spike counts were documented for the two icEEG contacts on either side of the microdialysis membrane, all contacts within 3cm of each probe, and all contacts within the region where the probe was located. Additionally, basal glutamate and basal glutamine values were correlated with the distance of the probe from the seizure onset area.
Results: The basal glutamate and basal glutamine values were negatively correlated with the probe distance to seizure onset area with correlation coefficient values of 0.2 ($p=0.06$) and 0.4 ($p=0.001$), respectively. We observed a slightly negative correlation between the basal glutamate values and spike counts. The correlation coefficient values for the probe contacts, contacts within 3cm, and regional contacts were 0.07, 0.08, and 0.14, respectively. In areas of high spiking, basal glutamate values were particularly low.

Discussion: The higher basal glutamate and glutamine values closer to the seizure onset area suggest a correlation between increased glutamate and glutamine levels and the seizure onset area. Spikes are traditionally though to indicate brain excitation. The slight negative correlation observed between basal glutamate level and spike counts, however, support the suggestion that spikes may instead be a measure of brain inhibition.
Conclusions: This study suggests considerable value for co-local *in-vivo* measurements of electrophysiology and neurochemistry to improve our understanding of the two modalities and the seizure onset area in patients with medically intractable epilepsy.

Title: Intracranial depth electrode recordings with fine spatial and temporal resolution show neural correlates of movement in humans

Authors: M. KERR[1,2], H.-J. PARK[2], K. KAHN[1], J. BULACIO[2], J. GONZALEZ-MARTINEZ[2], *S. V. SARMA[1], J. GALE[2];
[1]Biomed. Engin., Johns Hopkins Univ., Baltimore, MD; [2]Clin. Neurosci., Cleveland Clin., Cleveland, OH

Abstract: Most neural data collected from humans takes the form of electroencephalogram (EEG) or functional magnetic resonance imaging (fMRI). EEG provides high temporal resolution but poor spatial resolution, while fMRI provides high spatial resolution but low temporal resolution. To achieve both high temporal and spatial resolution, electrodes in the various brain structures are usually implanted in animal subjects. However in a small fraction of patients with refractory epilepsy, intracranial depth electrodes precisely guided by stereotaxis, a procedure known as stereoelectroencephalography (SEEG), are implanted as a means of identifying the epileptogenic area. SEEG recordings include tens to hundreds of channels that are distributed in deep and peripheral brain structures and therefore have fine spatial and temporal

resolution. This gives us a unique opportunity to study the human brain and neural correlates of behavior.
In this preliminary study, a patient implanted with 12 electrodes (113 channels), spatially distributed over cortex and deep structures, was asked to perform a joystick based motor task. The task involved moving a cursor to two consecutively presented circular targets and then pressing a button when cued. A measure of high frequency activity (HFA) was used as a proxy for neural activity in the region around each channel. HFA was calculated by averaging the normalized power in each 10 Hz band between 50 and 150 Hz.
Data show clear trial-by-trial activity modulations responding to new target presentation and task type instructions (angular gyrus), button-pressing (insula), and reward (middle temporal gyrus). For example, whenever a new movement target is presented, HFA modulated in the angular gyrus and robustly increased by approximately 80% from trial baseline with the effect lasting around 400 ms, supporting previous work implicating angular gyrus in shifts in spatial attention. These results demonstrate the achievable spatial and temporal resolution of SEEG combined with a behavioral task but also provide unique insight into the function of human brain.

Title: Neuronal stress responses are more related to APOE genotype than to stress modality or age

Authors: O. ABOUD[1], R. E. MRAK[2], F. A. BOOP[3], *S. T. GRIFFIN[1,4];
[1]Geriatrics, Univ. Ark Med. Sci., LITTLE ROCK, AR; [2]Pathology, Univ. of Toledo Hlth. Sci. Campus, Toledo, OH; [3]Neurosurg., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN; [4]Grecc, Central Arkansas Veterans Hlth. Care Syst., Little Rock, AR

Abstract: Precocious development of Alzheimer-type neuropathological changes in epilepsy patients, especially in *APOE* ε4 carriers is well known, suggesting the importance of investigating epilepsy-related neuropathological changes as they relate to each of the possible *APOE* allelic combinations. Frozen and paraffin-embedded tissue samples were resected from superior temporal lobes of 92 patients undergoing temporal lobectomies as a treatment for medication-resistant temporal lobe epilepsy (3 months- 73 years old, representing each of the *APOE* allelic combinations). Tissue samples were analyzed using immunofluorescence histochemistry, western immunoblot, and real-time PCR to determine genotype effects on neuronal number and size, neuronal and glial expressions of amyloid β (Aβ) precursor protein (βAPP), apolipoprotein E (ApoE), Aβ, S100B, interleukin-1α and β, and α and β secretases, and on markers of neuronal stress, including DNA/RNA damage and caspase 3 expression. Allelic combinations of *APOE* influenced each epilepsy-related neuronal and glial response measured. Patients with *APOE* ε3,3 genotype had larger neurons with less DNA fragmentation than other genotypes and greater numbers of activated IL-1-immunoreactive glia per neuron, suggesting neuronal resilience against stress. However, this resilience may foster plaque burden—25 % of those with *APOE* ε3,3 genotype (n=53) had plaques; no patient with even one *APOE* ε2 allele (n=15) had Aβ plaques, and neuronal size in patients having an *APOE* ε2 allele was, like those with *APOE* ε3,3 larger than in other genotypes. *APOE* ε4,4 conferred the weakest neuronal resilience in epilepsy. To determine if these epilepsy-related, *APOE* genotype dependent changes are similar to those in another neurological condition, analogous tissue samples from 10 autopsy-verified Alzheimer brains, and from 10 neurologically and neuropathologically normal (control) patients were analyzed with regard to neuronal size. As in epilepsy, Alzheimer patients with *APOE* ε4,4 had smaller neurons than did those with *APOE* ε3,3. Interestingly, there was no *APOE* genotype-dependent difference in these parameters in neurologically normal patients. Our findings provide evidence that the strength of the neuronal stress response is more related to patient *APOE* genotype than to either the etiology of the stress or to the age of the patient and are consistent with the idea that hyperexcitation elicits compensatory responses aimed at neuron repair and survival; but when chronic, these events may give rise to the precocious appearance of neuropathological changes, suggesting that *APOE* genotyping may be a useful tool in treatment decisions.

Title: Detecting preseizure states in intracranial EEG data using an adaptation of diffusion maps

Authors: *D. DUNCAN, R. TALMON, H. P. ZAVERI, R. R. COIFMAN;
Yale Univ., New Haven, CT

Abstract: Rationale: We studied the variability of the statistics of the icEEG data of patients with epilepsy over time to distinguish between different states of a patient. Diffusion mapping, which is one of the leading manifold learning methods, provides dimensionality reduction of the data as well as pattern recognition that can be used to distinguish different states of a patient. A new algorithm, which is an adaptation of diffusion maps, is developed to construct coordinates that generate efficient geometric representations of the complex structures in the icEEG data. Moreover, the combination of local covariance matrices and the Mahalanobis distance in the algorithm is used to remove the noise from the data to extract the underlying brain activity.
Methods: Intracranial EEG data were collected from a patient with localization related epilepsy who was undergoing presurgical evaluation at the Yale-New Haven Hospital. The seizure onset area was located on the right occipital lobe. We focus on the 3 electrode contacts that overlaid the seizure onset area and use our algorithm to distinguish interictal and preseizure states from 7 seizure episodes.
Results: Numerical results show that the proposed approach provides a distinction between interictal and preseizure states by constructing a mapping that separates data along these two classes. Once we have learned the mapping, it can quickly be applied to new data for classification in real time.
Conclusions: Based on the variability of the statistics of the data, we were able to show a distinction between interictal and preseizure states. The combination of the local statistics and the Mahalanobis distance is shown to be beneficial for such noisy data. Our goal is to define a threshold that separates the interictal state from the preseizure state in a wide range of cases and develop an automatic method to predict seizures.

Title: Predicting when MRI and FDG-PET will exhibit epileptogenic findings

Authors: *W. T. KERR[1], A. TREFLER[2], K. R. RAMAN[2], E. S. HWANG[2], N. SALAMON[3], M. S. COHEN[4];
[1]UCLA Semel Inst., Los Angeles, CA; [2]Psychiatry, [3]Neurology, Radiology, [4]Psychiatry, Neurology, Biomed. Engineering, Radiological Sciences, Biomed. Physics, UCLA, Los Angeles, CA

Abstract: The seizure onset zone (SOZ) of uncontrolled or medication resistant seizures epilepsy (MRE) has been associated with congenital or disease-initiating structural and/or metabolism abnormalities as well as progressive changes. The progressive changes, most commonly, are focal atrophy, MRI T2 signal hyperintensity and progressive focal hypometabolism on FDG-PET. These progressive changes reflect cell death of inhibitory neurons, gliosis and metabolic dysfunction within neurons. The majority of patients have no observable changes after their first seizure. Conversely, roughly 75% of patients with long-standing MRE have observable structural and/or metabolic abnormalities that help localize their SOZ. This results in a clinical conundrum: when should neuroimaging be acquired from patients with seizures? In this work, we developed a quantitative estimate of the pre-test probability that neuroimaging will reveal a potentially diagnostic abnormality. We used a Bayesian logistic regression model based upon the duration of seizure disorder, seizure frequency, age, gender and the etiology and location of the seizures from over 450 patients with medication resistant epilepsy admitted for long term video-EEG monitoring. Our model confirms that the observed probability that an abnormality was present increased logarithmically with duration of the seizure disorder (95% CI odds ratio MRI 1.09-1.44, PET 1.01-1.88 per log year) and a definitive diagnosis of temporal lobe epilepsy (95% CI odds ratio MRI 1.18-3.09, PET 1.82-5.51), controlling for the other included factors. Interestingly, when compared to patients with non-epileptic seizures, there was no significant evidence that patients with extratemporal epilepsy were more likely to exhibit structural or metabolic abnormalities (95% CI odds ratio MRI 0.75-

1.79, PET 0.40-1.46). The lack of effect of seizure frequency compared to duration of seizure disorder suggests that the characteristic cell death, gliosis and metabolic dysfunction was not associated with the number of seizure events, but instead with the chronic propensity to have these events. While our primary research aim was to improve the cost-benefit ratio of expensive clinical imaging, these data also help elucidate some of the pathologic mechanism behind why resective surgery for epilepsy was more effective earlier in a patient's course of disease.

Title: Effect of parent gender and education on the quality of life in pediatric epilepsy-results of an outpatient cross sectional study

Authors: M. IQBAL[1], S. AMIRSALARI[2], *M. RAZA[3];
[1]Fac. of Medicine,, [2]Dept. of Pediatrics, [3]Section of Neurosciences, Dept. of Neurology, Fac. of Med., Baqiyatallah Univ. of Med. Sci., Tehran, Iran, Islamic Republic of

Abstract: Introduction: In developing countries lacking modernized healthcare system, quality of life (QOL) and general health (GH) of pediatric epilepsy patients depends heavily on parental care and family support. Studying factors that affect QOL can help their parents and health care providers to plan their life better. We assessed parental factors affecting QOL of pediatric epilepsy patients in outpatient setting.
Methods: A cross-sectional survey of pediatric epilepsy patients (n=91, 49 M, 42 F, age 10.2 ± 0.3 y) was carried out using US quality of life in childhood epilepsy (QOLCH) and Seizure Severity Questionnaire (SSQ). Patients and their parents were interviewed at the outpatient pediatric neurology clinic. Patients with progressive neurodegenerative disorder, severe to profound mental retardation, or visual/hearing impairment were excluded from the study. Basic demographic data, type of epilepsy, seizure frequency, severity and other characteristics and social life of patients were recorded. Relevant data were graded using Likart scale and analyzed.
Results: The most common seizure type among patients was Complex Partial Seizure (CPS, n=39, 37.4%) followed by Generalized Tonic-clonic Seizure (GTCS, n=16, 17.6%). Neither QOL nor the GH of patients was related to the type of seizure. Total QOL in male patients with a

High school level of education in father was significantly different from those whose father's level of education was MSc (2.96±.131 vs 4±.316, p<.05) but father's education had no significant impact on QOL of female patients. Mother's level of education had no significant effect on QOL of patients. The overall GH in male patients with a high school level of education in mother was significantly different from those whose mother's level of education was BSc (3.24±.125 vs 2.25±.313, p<.05). Totally also, GH was significantly different in patients with a high school level of education in mother with those whose mother had a BSc level of education (3.13±.104 vs 2.36±.225, p<.05). GH in male patients whose father had a high school level of education was significantly different from those whose father had a MSc level of education (3.21±.157 vs 2±447, p<.05). The GH and QOL in patients significantly correlated with each other (Spearman) in both male (r=.4) and female(r=.3) patients. These two factors were totally correlated with each other also. There was a significant correlation between GH and number of seizures during recent week (Spearman, r=.215).
Conclusion: Parental gender and education has significant impact on the QOL and GH of pediatric epilepsy patients. Family education about epilepsy can help epileptic patients to have a better life.

Title: Spatial organization of the mapk signaling interactome in human epileptic brain

Authors: *S. BAGLA[1], J. LOEB[2];
[1]CMMG, Wayne State Univ., Detroit, MI; [2]Univ. of Illinois Chicago, Chicago, IL

Abstract: Epilepsy is a disease of recurrent seizures, however, the exact mechanisms and networks that produce epileptic activities in the neocortex are not known. Surgical removal of the focal brain regions that display a variety of epileptic activities presents an excellent opportunity to discover the molecular and cellular basis of human epilepsy. We have taken a high-throughput genomic approach and identified a highly consistent group of differentially expressed genes that correspond to these epileptic regions. Highly represented in regions that show high interictal spiking are genes that implicate MAPK/CREB signaling, Immediate Early

Genes (IEGs), and synaptic plasticity genes. Bioinformatic analyses showed a number of clusters within the MAPK/CREB genes that included both activators and inhibitors of MAPK signaling, raising an important question as to why both activators and inhibitors are both induced. As a means to answer this, we mapped these activators and inhibitors in human epileptic neocortical foci using in situ hybridizations and immunolabeling. One of the interesting inhibitors of MAPK/CREB that was significantly upregulated in our microarrays was DUSP4, a member of Dual Specificity Phosphatases, which acts by targeting both isoforms of ERK1/2. In situ hybridization studies of serial brain sections shows that DUSP4 is expressed in discrete micro-domains in the superficial neocortical layers. DUSP4 expression was inversely related to di-phosphoERK, phosphoCREB, EGR1, and DUSP6, suggesting that DUSP4 activation in regions of high interictal activity directly inhibits the spread of electrical activity in these focal regions. To test this, we developed a model that uses repeated depolarization of human neuronal Sy5Y cells to determine the mechanism of action of DUSP4. We found induction of DUSP4 protein within several hours of chronic depolarization, irrespective of CREB activation. These studies utilizing high throughput genomic studies from human neocortex begin to define both the mechanistic and spatial roles of MAPK signaling in neocortical epilepsy and that have the potential to produce novel therapeutics.

Abstract: The Brain Derived Neurotrophic Factor (BDNF) has been strongly implicated in the maintenance of the cytoarchitecture of mammalian hippocampus. In temporal lobe epilepsy (TLE), hippocampus has been proposed as an important brain structure for the onset and propagation of electrical discharges. In TLE patients, especially in those showing hippocampal sclerosis (HS), an increment of the genetic expression and protein levels of BDNF has been reported. Moreover, in vitro and in vivo BDNF administration in the nervous tissue of rodents has been associated with the HS phenotype. Human BDNF gene has a highly complex regulated expression leading to the synthesis of at least 17 different transcripts. The aim of the present study was to evaluate the levels of BDNF transcripts I, II, IV and VI in hippocampus of TLE -HS patients in comparison to TLE associated to brain lesions (i.e. infections, tumors, cavernomas). Method: Total ARN was extracted from HS (n=12) and lesions (n=8) hippocampus samples of TLE patients after surgery. The aforementioned transcripts were evaluated by quantitative Real-Time PCR, using the TATA binding protein as the reference gene (Taqman pre-designed assays). T student test was used to compare mean between groups. Results: An increment in the expression of transcript IV (p=0.04), as well as a tendency in the same direction for exons II (p=0.08) and VI (p=0.06 was found in patient with HS compared to those with lesions. Conclusions: These results are in accordance with recent animal models and human reports, indicating that the differential expression of BDNF gene could be a molecular mechanism of relevance in TLE.

Toronto, ON, Canada; [3]Stanford Synchrotron Radiation Lightsource, Menlo Park, CA; [4]Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: Changes in metals such as zinc have been observed in brains following seizures. The modulation of brain metal levels have also been known to initiate seizures. The precise interaction of endogenous metals and seizures, however, is not well understood and studies have been limited in their ability to study the co-occurrence of metals within the same epileptic structures. Previously we have demonstrated the use of synchrotron x-ray fluorescence imaging (SXRF) to characterize multiple metal distributions at multiple spatial scales in human cortical tissue (n = 17) recovered after minimally invasive epilepsy surgery. In this study, we examine the distribution and co-localization of elements within hippocampal regions of seizure foci, removed during surgery. Resected hippocampal tissue from surgical cases of patients with intractable mesial temporal lobe epilepsy (MTLE) were imaged using rapid-scanning SXRF and microprobe imaging (beamlines 10-2 and 2-3) at the Stanford Synchrotron Radiation Lightsource (n=7). Complete XRF spectra were captured for each pixel, allowing for whole image construction of any non-windowed element. Using SXRF imaging we were able to ascertain co-localized metals and perform quantitative analysis on a suite of elements. SXRF imaging showed definitive structure of the molecular and pyramidal cell layers of the hippocampus with a number of metals including iron and zinc. Large iron depositions were observed in several subjects with sclerotic hippocampal tissue. Analysis is underway to determine the iron species, an indication of the physiological process or potential indications of pathological damage to brain structure. These imaging studies of local circuitry thus help identify the role of brain metals in epilepsy while increasing our understanding of healthy brain structures from the perspective of endogenous brain chemistry.

Title: Profiles of BDNF/TrkB signaling pathways in human hypothalamic hamartoma tissues

Authors: S. SEMAAN[1], J. WU[2], *Y. CHANG[2], Y. HUANG[1];
[1]OB/GYN, St. Joseph's Hosp. and Med. Ctr., Phoenix, AZ; [2]Barrow Neurolog. Inst., St. Joseph's Hosp. & Med. Ctr., PHOENIX, AZ

Abstract: Human hypothalamic hamartoma (HH) is characterized by gelastic seizures, refractory to antiepileptic drugs. Evidence suggests that the source of seizures in HH patients lies within the lesion itself. Thus, identification of the potential mechanisms of epileptogenesis within HH tissues will aid the drug development for better management of this disease. Brain-derived neurotrophic factor (BDNF) that is essential for neuronal development and maintenance has been implicated in the modulation of synaptic function and plasticity. BDNF exerts its biological effects via binding to the TrkB receptor, subsequently engaging downstream signaling cascades, such as the MAPK (mitogen-activated protein kinase), Akt (protein kinase B), and PLCγ/CaMKII (calcium-calmodulin kinase II) pathways. In this study, we evaluated the major BDNF/TrkB signaling pathways in surgically resected HH tissues (n=14) versus human hypothalamic control tissues (n=8). Our results showed that phosphorylation of TrkB at Tyr816 was enhanced in HH tissues compared to the controls (P=0.015). By examining the MAPK pathways (ERK, p38, and JNK), we found that activation of all three MAPKs was elevated in HH cases than in the controls (pERK1/2, P=0.016; p-p38, P=0.049; pJNK1, P=0.001). For the Akt pathway, our results indicated that the level of active Akt (pAkt Ser473) in HH group was higher than that in the control group ($P < 0.05$). Surprisingly, the expression of PTEN (a suppressor of Akt) was also increased in HH compared to the control ($P < 0.05$). We further examined the correlation between PTEN and active Akt levels within HH group. Interestingly, a negative correlation between them was obtained, which could resulted in a further classification of the HH cases (n=14) into two subgroups (high PTEN/low pAkt and low PTEN/high pAkt). When assessing the PLCγ/CaMKII pathway, we observed that both CaMKII expression and PLCγ1 phosphorylation (pPLCγ1 Ser1248) levels were higher in HH than in the control group (CaMKII, P=0.004; pPLCγ1, P=0.00002). Finally, real-time RT-PCR results demonstrated an approximately 2.5-fold increase in BNDF mRNA expression in HH versus control tissues. Collectively, our findings suggest that multiple BDNF/TrkB signaling cascades are activated within HH lesion, which may independently and/or collaboratively contribute to epileptogenesis.

Title: Operant processes suppress epileptic processes

Authors: *J. C. NEILL[1], N. ALVAREZ[2];
[1]Psychology, Long Island Univ., GREENVALE, NY; [2]Neurol., Children's Hospital, Boston, Boston, MA

Abstract: What environmental events change epileptic processes? Earlier work from my lab demonstrated that prompts and rewards for active behavior in the everyday environment were correlated with decreases in the duration and frequency of epileptiform EEG and seizures in subjects with intractable generalized epilepsy and intellectual disability. Hypothetically, this effect was due to operant conditioning of behavior established by the everyday environment. To test this hypothesis, three subjects were monitored with concurrent EEG and video while resting, during operant conditioning and a go left-go right discrimination, and after conditioning sessions. Results from one representative subject will be discussed. During resting conditions, before operant conditioning began, the ED (percentage of time with epileptiform EEG discharges) was as high as 60%. During 5 operant conditioning sessions, in which operant responses were reinforced with variable interval schedules of reinforcement, ED was greatest (58%) before the conditioning sessions, moderate (15%) during the sessions, and minimal (4%) after the sessions. ED following sessions declined over 5 sessions of operant conditioning. When responding was stable, a sound source (pulsed white noise) was used to signal the response side producing reinforcement. In the first 12 sessions of auditory stimulus control training, control of responding increased from chance levels in session 1 to over 90% in session 12; simultaneously, during these sessions, ED was suppressed, from a high of 45% before session 2, down to 0 before session 12. During 12 sessions that it took for auditory stimulus control to reach asymptote, maximal ED was largest before conditioning sessions (45%), moderate during conditioning (25%), and lowest after training (12%). During session 12, when asymptotic auditory stimulus control was achieved, ED was 0 before, during, and after the session. The sound was then presented during ED to determine the effects of ED on response accuracy, which declined from 100% to chance levels. When discriminative stimuli were presented during ED, ED increased before, during and after sessions. Conclusions: ED can be suppressed by operant processes, including reinforcement and stimulus control. When frequent reinforcement is presented for operant behavior in the absence of ED, ED decreases, especially after discrimination training, and this effect persists in the training context. Similar results were obtained in all three subjects. Concurrent EEG and behavioral intervention offers a mature, useful and effective non-pharmacological intervention to substantially suppress seizures.

Title: Prospective testing of driving during clinical and subclinical seizures in patients with epilepsy

Authors: *W. CHEN[1], A. BAUERSCHMIDT[1], M. W. YOUNGBLOOD[1], C. CUNNINGHAM[2], C. EZEANI[2], Z. KRATOCHVIL[2], J. BRONEN[2], J. THOMSON[2], K. RIORDAN[2], J. Y. YOO[2], R. SHIRKA[2], L. MANGANAS[2], L. J. HIRSCH[2], H. BLUMENFELD[2];
[2]Neurol., [1]Yale Sch. of Med., New Haven, CT

Abstract: Epileptic seizures, especially when associated with loss of consciousness, can significantly limit the ability of affected individuals to lead normal, independent lives. Because seizures are often associated with loss of motor control and loss of consciousness, people with epilepsy (PWE) are restricted from driving until it can be shown that seizures are fully controlled. In the U.S. and elsewhere, driving license issuance is dependent on PWE maintaining a seizure-free period whose length depends on local laws. The individual's physician plays an important role in determining whether or not the patient should be allowed to drive. However, these decisions are difficult because little objective data are available about patient driving ability during seizures. In this study we analyzed ictal and interictal performance data captured prospectively from a driving simulator in patients undergoing continuous video/EEG monitoring. A total of 33 seizures in 20 patients were analyzed. Driving performance data during interictal periods were used as baselines in comparison to ictal driving performance. A set of quantitative criteria were used to determine the presence of impairment. These included car velocity, steering wheel movement, and application of the brake pedal, as well as whether crashes occurred. We found that seizures were associated with a higher rate of crashes than driving on the same portions of the track in the interictal period . In addition, longer duration of partial seizures was related to more severe impairment in driving. Subclinical electrographic seizures were not associated with obvious driving impairment. Ongoing analyses will determine if more subtle impairments occur in subclinical seizures. These findings demonstrate the feasibility of testing

ictal driving in a prospective manner. In future work we hope to determine whether specific seizure types or localizations present a greater driving risk, with the goal of providing improved guidance to physicians and patients with epilepsy.

Title: Characteristic neuronal activities of patients with mesial temporal lobe epilepsy: an *In vitro* imaging study of the resected non-sclerotic hippocampus

Authors: *H. KITAURA[1], H. MASUDA[2], H. SHIMIZU[3], H. SHIROZU[2], H. MURAKAMI[2], H. TAKAHASHI[3], S. KAMEYAMA[2], A. KAKITA[3];

Abstract: Mesial temporal lobe epilepsy (MTLE) is the most frequent focal epileptic syndrome, and the vast majority of seizures originate from the mesial structures of the temporal lobe. Tissues surgically resected from the hippocampus usually exhibit severe neuronal loss, i.e. hippocampal sclerosis. Recently, however, we had the opportunity of examining histopathologically rare examples of hippocampus tissue taken from four patients with MTLE, where neuronal loss was not apparent. A brain MRI study of each patient demonstrated a tumor-like lesion in the uncus, a cavernous angioma in the uncus, slight atrophy of the unilateral hippocampus, and suspicious structural variation in the hippocampus, respectively. After surgical resection of the mesial temporal lobe, we investigated neuronal

activity in freshly prepared slices of the relatively well preserved hippocampi employing flavoprotein fluorescence imaging *in vitro*. As a control, we retrieved two non-MTLE patients with cortical tubers or a scar lesion in the lateral temporal lobe, in whom the surgically resected hippocampi showed no histopathologic abnormalities. Morphometric analysis disclosed no significant differences in the number or size of the hippocampal pyramidal neurons between the MTLE and control patients. However, the neuronal activities detected in the slices differed. Although flavoprotein fluorescence responses were observed in all subfields in all patients, the amplitudes of the responses in the subiculum and CA1 were significantly larger in the MTLE patients than in the controls (mean ± SD (%); MTLE vs. control = 2.01 ± 0.32 vs. 0.79 ± 0.37, respectively in the subiculum, and 2.07 ± 0.83 vs. 0.83 ± 0.29, respectively in CA1). Local field potential recording demonstrated epileptiform spontaneous discharges in the subiculum and CA1 only in the MTLE patients. Moreover, the epileptiform activities had a clear high-frequency oscillation component, and surprisingly the discharge in the subiculum always preceded that in the CA1 by about 50 ms. Currently it is unclear whether the characteristic neuronal activities were specific for the MTLE patients we examined, or are universal in patients with the early stage of common MTLE. Further studies are needed to clarify the epileptogenic mechanisms in MTLE patients with hippocampal sclerosis. The present results suggest that in MTLE patients with no hippocampal sclerosis, epileptogenesis may occur in the subiculum.

Abstract:
Antiepileptic drugs are metabolized by enzymatic reactions of the family of cytochrome P450(CYP). Genetic variants lleles) of CYP affect plasma concentrations or antiepileptic drug exposure. CYP2D6 and CYP2C19 are polymorphic genes associated with metabolism that have been associated with underlying risks. The purpose of this work is to relate the concentration of antiepileptic drugs in blood and saliva metabolized by CYP450 polymorphisms in genes encoding these enzymes. We included 30 patients, 23 drug resistant and 7 drug-controlled, with an average age of 10 years and a predominance of women (60%) in both groups; 50% began at 3 years of age and 75% of the drug-presented their first crisis within their first nine years of life, one more than the controls. The treatment usedwas valproic acid; average dose ingested and 025.4mg/24h 1140mg/24h respectively. The saliva concentration was 2.3mg in the control group and 1.0 mg in the problem group; the concentration in blood plasma was of 82.1mg and 63.2mg respectively. The average consumption of valproic acid in 24h in the control group varied evenly between the minimum dose and maximum consumed (42mg). In the drug group, this difference increased to 620mg. However, according to the genetic variants, generally valproic acid concentrations in the saliva howed higher concentrations in the control group than in the refractory (average of 2.4 and 1.0 mg, respectively), and with respect to the average plasma it was 83.9mg in the control group and 65.1mg in the problem group. Frequencies of genetic variants of the SNP's tracked exons 1, 3, 5 and 6 of the CYP2D6 gene 4 and 5 of CYP2C19, showed an increased
prevalence in heterozygotes of all exons of the control group except in exon 5 CYP2D6 gene, likewise the refractory group showed heterogeneity in the prevalence of the variant studied exons. And for the gene CYP2C19, polymorphisms were identified only in heterosigota form, as expected. So far no relationship has been found between the SNP's and the drug concentration in plasma and saliva. The polymorphisms of CYP450 genes can contribute to an individualized therapy in epilepsy treatment.(Work supported by ICyT PFUT-08-027,FIS/IMSS/PROT/737 and fellow 103937 CONACYT).

Abstract: We previously reported identification of putative epilepsy susceptibility loci using data from a genome wide association study (GWAS). Since our initial data presentation, we genotyped additional samples and have thereby increased power to detect single nucleotide polymorphism (SNP) association from individuals of European (n=1364) and African (n=271) ancestry, all of whom passed rigorous quality control measures and are included in analyses reported here. Epilepsy subtypes included genetic generalized epilepsy (GGE: n=656 European, n=114 African) and non-symptomatic/cryptogenic focal epilepsy (CFE: n=708 European, n=157 African). DNA from healthy control individuals was used for comparison (European n = 6419, African n=2843). Samples were genotyped on the Illumina 550,610, and Omniexpress chips and 38 million variants were imputed with the 1000 genomes project haplotypes. Single-point contingency analysis was carried out using the European samples alone or in combination with samples of African ancestry comparing all patients with all controls, all CFE patients to all controls and all GGE patients to all controls. In a comparison between European GGE and matched controls, six linked markers in the PADI6 locus on chr1p36 reached p values suggestive of genetic association ($p<10^{-7}$) and the top marker reached genome wide significance (rs34018214, $p=4.97\times10^{-8}$). Several additional loci demonstrate suggestive association with GGE including markers on chr1 (CNIH3), chr4 (GRID2), chr6 (SLC35F1) and chr16 (XYLT1). Indeed, our prior data identified association at the MHY11/NDE1 gene locus at 16p13.11, a region within 2MB of XYLT1 and where deletions have been associated with seizures, intellectual disability, autism, and schizophrenia. Suggestive evidence for an association with

focal epilepsy was found on chr2 (RTN4), chr7 (SP8), chr9 (ZNF462), and chr19 (NUDT19). When GGE and CFE patients were combined, suggestive evidence for an association was identified on chr2 (GLS, NAB1) and chr20 (PTPRT). Copy number variation (CNV) analysis on this cohort is in progress and GWAS data sets from around the world are being combined for a meta-analysis that will include approximately 10,000 patients and 20,000 controls. It is anticipated that increased statistical power afforded by meta-analysis will confirm identified suggestive loci as bona fide epilepsy susceptibility genes. These new data confirm some earlier findings and identify new gene targets for further investigation in the pathophysiology of common forms of human epilepsy.

Politecnico Nacional, Mexico D.F, Mexico; [7]Ciencias Farmaceuticas, Univ. de la Republica, Montevideo, Uruguay

Abstract: One factor associated with drug resistance in epilepsy is genomic variability, as the presence of polymorphisms that produce alterations in the protein and P-glycoprotein (Pgp) encoded by the ABCB1 gene, which acts as an efflux pump in the blood brain barrier and controlling limiting entry drugs and toxins into the brain, various substrate antiepileptic drugs

(AEDs) like felmabato, gabapentin, lamotrigine, topiramate and phenytoin. Alterations are polymorphic; it may be generating alterations in the adsorption of AEDs.
The aim of this work was to identify the polymorphisms rs9282564, rs2229109, rs1128503, rs28381209, rs2032582, rs1045642 and rs28364274 ABCB1 gene in drug-resistant patients with TLE and its relationship to plasma levels and salivary DAEs.
Of the polymorphisms analyzed, 4 are present in Mexican pediatric population (rs2229109, rs1128503, rs2032582 and rs1045642). The SNPs C1236T was the most frequent (59.1%), with 61.5% homozygosity. This polymorphism is synonymous. The T2677G SNPs that changes a serine to alanine, was presented in 54.5% of the study population, with a ratio of 50% of heterozygotes and homozygotes. The third most frequently was polymorphism C3435T (48.6%), with a trend homozygous allele (53.8%). The G1199A SNPs was less frequent (9.09%). T2677G polymorphism had higher relationship with AEDs. However, no significant association was found between SNPs and drug ELT. However, in our study population was a tendency to present the C1236T polymorphism.
It is necessary to perform a study with a larger number of patients with this pathology with the most significant polymorphisms found in this study to identify the involvement of Pgp in drug-resistant epilepsy.

Title: A novel approach to model the consequences of non-adherence in newly diagnosed patients with epilepsy

Authors: *K. E. THOMSON[1], C. RUEDA[2], A. C. MODI[3], T. A. GLAUSER[4], S. WHITE[2]; [1]Anticonvulsant Drug Develop. Program, SALT LAKE CTY, UT; [2]Pharmacol. and Toxicology, Univ. of Utah, SALT LAKE CTY, UT; [3]Div. of Behavioral Med. and Clin. Psychology, [4]Neurol., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Epilepsy is a debilitating seizure disorder that can profoundly impact quality of life. It is estimated that 38% of patients with epilepsy do not have adequate seizure control with their current anti-seizure drug (ASD) regimen. This percentage has remained relatively constant over the past 20 years, despite 20 new ASD compounds made available. However, it is not known whether non-adherence to the ASD regimen directly contributes to poor seizure control and the development of therapy resistance. Clinical results have suggested that early non-adherence is associated with differential long term seizure control. However, these results are confounded by many factors, including inaccurate self-reporting of seizures, patient overestimation of adherence, and the various etiologies and severities of human epilepsy. As such, it is difficult to directly evaluate the effects of non-adherence on the occurrence of seizures. There is evidence in the field of epilepsy research that quick withdrawal of an ASD medication leads to the precipitation of seizures, that seizures lead to more seizures, and that a higher seizure burden leads to therapy resistant epilepsy. Taken together, these three pieces of evidence suggest the hypothesis that non-adherence behaviors may be detrimental to seizure control. Given the problems associated with testing this hypothesis in the clinical setting, we have developed a unique approach using an established animal model to test the impact of non-adherence on seizure control.
We have designed a novel computer-automated medication-dosing system using a carbamazepine(CBZ)-in-food protocol (75 mg/kg p.o., QID). An excess number of Sprague Dawley rats were implanted with EEG electrodes and treated with low-dose kainate to permit a minimum of 8 epileptic rats enrolled into each experimental arm. After their first observed spontaneous convulsive (Racine Stage 3+) seizure, the animal was randomly enrolled into one of three treatment groups; 100% medication, no medication, or a randomized pattern of 50% adherence for the remaining 6 weeks of the study. This is the first study to use an animal model to study the impact of human non-adherence patterns on seizure control. Our preliminary results suggest that non-adherence to the prescribed ASD regimen employed in this study may contribute to poor seizure control. The development of a computer controlled automated feeder system and the use of newly diagnosed epileptic rats into a clinical protocol designed to mimic the management of newly diagnosed epilepsy will provide new insight into the impact of non-adherence on seizure control and development of therapy resistance.

Title: Rats with epilepsy reinforce poor spatial information during sleep following a spatial task

Authors: *A. S. TITIZ, M. MAHONEY, M. TESTORF, P.-P. LENCK-SANTINI, G. HOLMES, R. SCOTT;
Neurol., Geisel Sch. of Med. at Dartmouth, Lebanon, NH

Abstract: Memory impairment is a major problem in patients with temporal lobe epilepsy (TLE) which is accompanied by disturbances in sleep. As sleep is critical for memory consolidation, we hypothesized that rats with TLE would have impairments in the sleep reactivation of neuronal patterns observed during behavior. In this study, we recorded place cells while animals were running in a circular track and then evaluated the reactivation of the neuronal patterns observed in the following sleep period. Place cell coherence was decreased in animals with TLE ($p < 0.05$). Despite poor quality place cells, we show evidence for normal neuronal reactivation in epileptic rats using a correlation approach. We then examined the sequential activation of place cells during population bursts in sleep and found that in both groups of animals these bursts are represented by high-order Markov Chains (i.e., four- and five-grams) similar to the sequences observed in behavior. Thus, the reactivation system appears to remain intact in animals with TLE despite severe cell loss and recurrent epileptiform activity. Therefore, sleep related memory processing in the hippocampus may be intact in the pilocarpine model of TLE. We propose that the memory impairments TLE may be at least in part a result of consolidation of poor spatial information encoded in the hippocampus during behavior.

Title: Genetic modifiers of generalized epilepsy mutations in mice

Authors: *W. N. FRANKEL, T. C. MCGARR, C. L. MAHAFFEY, B. J. BEYER, V. A. LETTS;
The Jackson Lab., BAR HARBOR, ME

Abstract: Epilepsy is a genetically complex disease. Even so-called Mendelian gene effects can be influenced profoundly by other genetic variants in an individual's genome. Identifying and understanding how natural variants modify disease should provide insight towards treatments or cures. Unbiased approaches such as forward genetics increase the chance that these discoveries will be novel or unexpected.
We have studied mutant genes that cause absence seizures in mice, including *Gria4* (AMPA receptor subunit 4), *Scn8a* (sodium channel $Na_v1.6$) and *Gabrg2* (GABA-A receptor subunit gamma 2). Genetic modifiers are clearly at play in each: on the C57BL/6J (B6J) strain background compared with C3HeB/FeJ (FeJ) each presents a significantly mitigated phenotype in the EEG - fewer spike-wave discharges (SWD), shorter average duration. To investigate whether these modifiers are shared or private, we performed genetic mapping and validated several chromosomal regions. *Gabrg2* and *Gria4* mutations appear to share a major modifier on Chr 6 (in the process of being confirmed). *Gria4* has a major "private" modifier on Chr 15 (confirmed in a congenic strain). *Scn8a* does not appear to share a modifier with the other two mutations, but has its own private modifier on Chr 7 (also confirmed). We recently completed RNAseq gene expression from thalamus and cortex in B6J and FeJ and have begun testing both novel and known candidate genes within mapped modifier regions.
Beyond major strain differences, even mouse substrains may show modifier effects. SWD due by *Gria4* mutation are more mitigated on the C3H substrain HeJ compared with FeJ – these are very closely related except for recent genetic drift; in C3H strains a major cause of *de novo* events are IAP retrotransposon insertion mutations. We identified a HeJ-specific insertion in a gene that encodes a conserved, novel transmembrane protein, and exploited TALEN technology to create a new frameshift mutation in FeJ. Our preliminary results suggest that this gene is responsible for at least some of the substrain difference. We are confirming and examining this gene in greater detail and determining whether it also affects the phenotype of other generalized epilepsy mutations. We hope that this and other novel or unexpected discoveries will add to the armament of new tools to understand and treat seizure disorders.

Title: Psychoneurochemical investigations to reveal neurobiology of depression, learning and memory deficit in epilepsy

Authors: *R. K. GOEL[1], A. MISHRA[2];
[1]Professor,, Patiala, India; [2]Pharmaceut. Sci. and Drug research, Punjabi Univ., Patiala, India

Abstract: Exploration of neurochemical changes in discrete brain parts linked to epileptogenesis and memory formation may help to understand the neurobiology of susceptibility to depression, learning and memory deficit in epileptic patients and progressive learning and memory deficit in uncontrolled or untreated patients with epilepsy. In chronic epileptic patients, ictal and postictal states are relative momentary than interictal state, which persists for longer time. As the time span of the interictal state prevails over postictal state, the monitoring of behavioral and neurochemical changes in the interictal state may be crucial to provide valuable insight for the pathology of susceptibility of learning and memory deficit in epilepsy. While for understanding the neurobiology of progressive depression, learning and memory deficit in uncontrolled seizures neurochemical changes may be monitored after multiple convulsive episodes. Therefore the present study was executed to explore the possible targets for comprehensive management of this problem.

Kindling was induced by administering subconvulsive dose of pentylenetetrazole (35 mg/kg; i.p.) at an interval of 48±2 h. Only successfully kindled animals were included in the study and divided into two groups (interictal and postictal group), while non-kindled animals served as naïve group. In postictal group, animals were challenged with pentylenetetrazole (35 mg/kg) on days 5, 10, 15 and 20. Depression and learning and memory were evaluated on days 5, 10, 15 and 20. After behavioral evaluations on day 20, all animals were sacrificed to remove their brains for estimation of glutamate, GABA, norepinephrine, dopamine, serotonin, acetylcholinesterase activity and total nitrite.

The results of the study suggest that pentylenetetrazole-kindling in mice associated depression like behavior, learning and memory deficit in interictal group and progressive memory deficit in postictal group. Neurochemical changes suggest, reduction in monoamines level and elevation in nitrosative stress and acetylcholinesterase activity in hippocampus and cortex as a possible pathogenic mechanism, apart from glutamate/GABAergic hypothesis, for the development of depression, learning and memory impairment in chronic model of experimental epilepsy. Further, selective enhancement hippocampal and cortical monoamines level may be useful as comprehensive target and reduction in nitrosative stress and acetylcholinesterase activity in hippocampus and cortex may be useful as adjuvant targets with antiepileptic drugs for the management of depression, learning and memory deficit in epilepsy.

Title: Early life seizures in female rats lead to anxiety-related and abnormal social behaviors

Authors: *R. M. CYSNEIROS, A. S. S. CASTELHANO, G. S. T. CASSANE;
Univ. Presbiteriana Mackenzie, Sao Paulo, Brazil

Abstract: Neonatal seizures are the most common manifestation of neurological dysfunction in the neonate. Animal data indicates that seizures during development are associated with a high probability of long-term adverse effects such as learning and memory impairment and behavioral changes. Previously, we reported that a single episode of neonatal status epilepticus (SE) impaired social play behavior in male rats (Castelhano et al., 2010), increased emotionality and impaired sociability with no locomotor activity changes (Castelhano et al., 2013, in press). We evaluated the sociability and anxiety-like behaviour of female rats submitted to neonatal SE. Experimental group (EXP) received pilocarpine (380 mg/kg, i.p) and control group (CTR) received saline at postnatal day 9. Behavioral studies started at 60 days postnatal. To the time of immobility, we noted a significant effect of group ($F[1.22]= 23.41$; $p< 0.0001$) and of the exposure in the open field´s arena (1st X 2nd, $F[1.22]= 45.21$; $p< 0.0001$), and no effect of interaction ($F[1.22]= 3.34$, NS). EXP exhibited higher time of immobility comparatively to CTR in both exposures with reduced central locomotor activity ($F[1.22]= 24.18$; $p<0.0001$). However, the total locomotion did not differ between groups ($F[1,22]= 0.57$; NS), suggesting the presence of increased emotionality with no alterations in general locomotor activity. The sociability was investigated measuring the tendency of the rat to approach an unfamiliar rat and engage in social investigation. With the introduction of an unfamiliar rat into one of the compartments, EXP exhibited less number of entries as compared to the CTR into the compartments ($F[1.22]= 45.90$, $p <0.0001$), but not between compartments ($F[1.22]= 0.53$; NS), and a significant effect of interaction was noted for time spent into compartments ($F[1.22]= 12.58$; $p=0.0018$). CTR spent

more time with unfamiliar rat than with object and EXP did not show interest for social encounter. With an introduction of a novel rat into another wire cage, EXP exhibited fewer number of entries into compartments ($F[1.22]=92.45; p<0.0001$), but not between compartments ($F[1.22]=3.61$; NS and). For time spent into compartments, a significant effect of interaction was noted ($F[1.22]= 39.66$; $p<0.0001$). CTR spent more time with a novel rat and EXP did not exhibit motivation for social novelty. For snout-snout contacts a significant effect of interaction was noted ($F [1.22]= 79.11$, $p<0.0001$). CTR exhibited more preference for the social novelty than EXP. The data suggest that neonatal SE in rodents leads to altered anxiety-related and abnormal social behaviors.

Title: Focal epileptiform activity in the prefrontal cortex is associated with long-term attention and sociablity deficits

Authors: *A. E. HERNAN[1], A. ALEXANDER[1], K. JENKS[1], J. BARRY[1], P.-P. J. LENCK-SANTINI[1], E. ISAEVA[1,2], G. L. HOLMES[1], R. C. SCOTT[1,3];
[1]Neurol., Geisel Sch. of Med. at Dartmouth, Lebanon, NH; [2]State Key Lab. for Mol. and Cell. Biol., Kiev, Ukraine; [3]Inst. of Child Hlth., Univ. Col. London, London, United Kingdom

Abstract: There is a well-described association between childhood epilepsy and pervasive cognitive and behavioral deficits including working memory impairments, ADHD and autism

spectrum disorder. However, the precise role of epileptiform discharges in these deficits remains unclear. In order to understand the relationship between frequent epileptic discharges during the neurodevelopmental period and cognition later in life, we developed a model of frequent focal interictal spikes (IIS). Postnatal day (p) 21 rat pups received intracortical injections of bicuculline methiodine into the prefrontal cortex (PFC) while EEG was continuously recorded. Within seconds of injection, focal spikes were recorded at the injection site. Injections were repeated in order to achieve 5 days of IIS. Short-term plasticity (STP) and behavioral outcomes were studied. IIS resulted in a significant increase in STP bilaterally in the PFC. In a delayed non-match-to-sample task IIS rats showed marked inattentiveness without deficits in working memory. Rats also demonstrated deficits in sociability. No changes in motivation, hyperactivity or anxiety were seen. We conclude that early-life focal IIS in the PFC have long-term consequences for cognition and behavior at a time when IIS are no longer present. Focal IIS during development can disrupt neural networks, lead to long-term deficits and thus may have important implications in attention deficit disorder and autism.

Title: Mossy fiber sprouting in the BDNF-enriched hippocampus

Authors: *K. M. GUTHRIE, C. AYDIN, C. PARE, C. ISGOR;
Dept Biomed Sci., Florida Atlantic Univ., BOCA RATON, FL

Abstract: Structural changes that alter hippocampal functional circuitry are implicated in learning impairments, epilepsy, and mood disorders. Sprouting of mossy fiber (MF) axon collaterals from dentate gyrus granule cells (GCs) is one such form of plasticity that results in expanded innervation of the supragranular layer and CA3 pyramidal neurons. Hippocampal levels of the neurotrophin brain-derived neurotrophic factor (BDNF) are regulated by activity,

and seizures increase BDNF expression, as well as TrkB receptor activation, in the MF-CA3 projection. Seizure activity also promotes MF sprouting, implicating BDNF signaling in this structural response. In transgenic mice with reduced BDNF levels/TrkB signaling, seizure induction and MF sprouting are suppressed. Mice overexpressing BDNF under the beta-actin promoter show increased seizure susceptibility, and enhanced GC dendritic complexity, but surprisingly, no MF sprouting out to 6 months of age. Mice that overexpress BDNF under the alpha-calcium/calmodulin-dependent protein kinase IIa promoter (termed TgBDNF mice) show an age-dependent emergence of epileptogenesis, with spontaneous seizures developing at ~5 months. Seizures are not observed earlier, but cognitive effects are evident by 2-3 months and include impairments in spatial memory. This suggests early circuit disruptions that may progress under the influence of chronically elevated BDNF to promote epileptogenesis. To determine if young adult TgBDNF mice show structural changes in hippocampus, we used Timm's method for silver sulfide staining and quantitative stereology to measure MF terminal field volumes in 8-week-old TgBDNF and wild-type mice. In situ hybridization and Western blotting were used to compare levels of hippocampal BDNF and TrkB-mediated signaling. TgBDNF mice showed a ~5-fold increase in mature BDNF, with no significant changes in steady-state levels of TrkB, ERK1/2, and PLC-gamma-1 phosphorylation. In contrast to beta-actin-BDNF mice, TgBDNF mice exhibited significant MF sprouting, as evidenced by 30% and 50% increases in terminal field volumes in the suprapyramidal and intra/infrapyramidal compartments, respectively. These data support a role for sustained increases in BDNF in the development of aberrant MF-CA3 functional connectivity.

Title: Electrophysiological properties of age-defined dentate granule cells in a rodent model of temporal lobe epilepsy

Authors: *A. L. ALTHAUS[1], H. ZHANG[2], E. MESSENGER[2], G. G. MURPHY[1,3,4], J. M. PARENT[1,2];
[1]Neurosci. Grad. Program, Univ. of Michigan, ANN ARBOR, MI; [2]Dept. of Neurol., [3]Dept. of Mol. and Integrative Physiol., [4]Mol. and Behavioral Neurosci. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: Dysregulated hippocampal neurogenesis is a prominent feature of temporal lobe epilepsy (TLE). Anatomical data indicate that most dentate granule cells (DGCs) generated in response to an epileptic insult develop features that promote increased excitability, including ectopic location, persistent hilar basal dendrites (HBDs) and mossy fiber sprouting. However, some appear to integrate normally and promote reduced excitability. Much of what is known about aberrant DGC neurogenesis comes from anatomical data; relatively few studies have investigated the physiological properties of age-defined cells. Using a retroviral (RV) GFP reporter to birthdate DGCs, our laboratory found that DGCs that were mature at status epilepticus (SE – the onset of epilepsy in this model) are resistant to morphological abnormalities, while the majority of those born after SE display TLE-related pathology. This may suggest that post-SE generated DGCs promote pathological function while established DGCs retain normal function. To examine the relationship between DGC age and activity within an epileptic network, we record from RV birth-dated DGCs born either neonatally, or during adulthood in an epileptic or intact animal. Recordings are made between 8-14 weeks after SE from age-defined cells in acute hippocampal slices using voltage-clamp. We find that, in TLE tissues, both adult-born and neonatal-born populations of DGCs receive increased excitatory input compared with age-matched controls in intact tissues. Ongoing analysis aims to determine whether there is a correlation between degree of aberrant morphology and amount of excitatory input. Concurrent experiments will assess inhibitory inputs within the same populations of cells. A separate set of experiments confirmed that intrinsic properties that influence excitability such as input resistance, membrane potential and action potential threshold are not different among groups.

Title: Inhibitory signaling to dentate granule cells following traumatic brain injury

Authors: *C. R. BUTLER[1], J. A. BOYCHUK[1], B. N. SMITH[1,2];
[1]Physiol., [2]Spinal Cord and Brain Injury Res. Ctr., Univ. of Kentucky, Lexington, KY

Abstract: Traumatic brain injury (TBI) is one of the most common causes of temporal lobe epilepsy (TLE). Changes in inhibitory signaling after CCI include hilar inhibitory neuron loss, synaptic reorganization, and GABA receptor subunit reorganization, all of which may support the development of spontaneous seizures following TBI. Here, a mouse model of posttraumatic epilepsy using controlled cortical impact (CCI; velocity= 3.5m/s; duration= 500 msec; depth= 1.0mm) was used to examine inhibitory signaling within the dentate gyrus 8-13 weeks after injury. Tonic and phasic GABAA receptor-mediated responses were assessed using whole cell patch-clamp recordings of dentate granule cells (DGCs) in slices from control and injured mice. Both tonic and phasic GABAA responses were studied in voltage clamp at baseline and during steady-state bath application of 4,5,6,7-tetrahydroisoxa-zolo[5,40c]pyridin-3-ol (THIP) (3 μM) followed by bicuculline (30 μM) to explore δ subunit containing GABAA receptor function in DGCs after TBI.
Preliminary results indicate no significant difference in the total basal tonic current uncovered with bicuculline application in DGCs between CCI-injured and sham-operated control mice, or between ipsilateral and contralateral hippocampi of injured mice. However, the tonic current in DGCs from the injured hemisphere of CCI mice exhibited reduced sensitivity to THIP, suggesting a decreased contribution of δ subunit-containing GABAA receptors to tonic current generation. No significant differences between CCI-injured mice and sham-operated controls were detected in spontaneous inhibitory postsynaptic current (sIPSC) amplitude or kinetics, either at baseline or during THIP application. Results suggest that tonic GABAA receptor-mediated currents are altered ipsilateral to the injury after CCI in mice, a response that involves reduced activity of δ subunit-containing GABAA receptors several weeks after injury. Ongoing studies will assess inhibitory signaling in DGCs at earlier time points after injury.

Title: Aberrant hippocampal neuron organization in the seizure-prone naked mole-rat

Authors: M. ZIONS[1], X. A. GEOFFROY[2], C. VICIDOMINI[3], *D. P. MCCLOSKEY[3,1,2];
[1]Doctoral Program in Neurosci., The Grad. Ctr. at CUNY, New York, NY; [2]Ctr. for Developmental Neurosci., Col. of Staten Island/CUNY, Staten Island, NY; [3]Dept of Psychology and Program in Developmental Neurosci., Col. Staten Island/ CUNY, STATEN ISLAND, NY

Abstract: The unique ecological niche and social organization of naked mole-rats (Heterocephalus Glaber) make them a useful model to study environmental, hormonal, and social factors related to epilepsy. But perhaps the most relevant feature that makes them a useful animal model of epilepsy is their spontaneous seizure activity; naked mole-rats housed in a laboratory setting demonstrate motor seizure behaviors. In an effort to understand the mechanisms driving these seizures, the present work examined the hippocampus as a likely candidate structure. Electrophysiological and anatomical studies suggest altered hippocampal circuitry that may be related to the observed seizure behaviors.

Single channel and multielectrode array recordings of acute hippocampal slices of naked mole-rats demonstrate unprovoked multifocal epileptiform burst discharges in over 90% of recorded animals. The bursts that originate in area CA3 are markedly similar to those we have previously recorded in pilocarpine-treated chronic epileptic rats. Stimulation of the mossy fiber pathway reveals an antidromic signal from CA3 to DG which is absent under TTX. CNQX abolishes the orthodromic response but does not eliminate the antidromic signal. Di-I and biocytin labeling in the hilus confirm the presence of CA3 pyramidal cells with axons heading toward the dentate gyrus.

Initial multielectrode recordings demonstrate that additional bursts are generated in the subiculum, producing prolonged epileptiform discharges which appear to be independent of CA3. We are exploring the implications of this restructured hippocampal circuitry with graph theory-based network analysis of single neuron interactions across the hippocampal slice; we also are confirming broader seizure activity with in vivo recording from live naked mole-rats.

Title: Development of corrupted dentate granule cell activation properties in a mouse model of temporal lobe epilepsy

Authors: *C. G. DENGLER[1], S. F. FRAUSTO[2], H. TAKANO[2], D. A. COULTER[1,2]; [1]Neurosci., Univ. of Pennsylvania, Philadelphia, PA; [2]Children's Hopsital of Philadelphia, Philadelphia, PA

Abstract: In addition to its contribution to cognitive function, the dentate gyrus also plays a critical role in regulating the activation of downstream structures in the hippocampus and limbic system, acting as a regulated gate restricting the relay of synchronous neuronal activity associated with epilepsy. Dentate granule cells (DGC) exhibit sparse, precise, and frequency-dependent network activation properties in vitro, which is consistent with in vivo observations. These properties of DGCs deteriorate in animal models of epilepsy. Here we investigated the time course of network activation properties of DGCs in the pilocarpine mouse model of temporal lobe epilepsy to determine if and how DGC activation is altered over the course of disease progression.

To accomplish this, we utilized multicellular calcium imaging to probe activation of DGCs responding to afferent stimulation in hippocampal entorhinal-cortex slices prepared from adult mice in a pilocarpine model of epilepsy. We recorded from naïve animals, animals early during epilepsy expression (2 weeks post status epilepticus, SE), and late-stage animals 6-12 months post SE. DGCs from both naïve animals and early stage animals exhibited sparse, frequency dependent activation of DGCs, with marked recruitment of DGCs at theta and gamma frequencies. However, DGCs from late-stage epileptic animals exhibited significantly higher proportional activation and the frequency dependence of this activation was degraded, with robust recruitment of DGC activity at all frequencies tested. Naïve DGCs exhibited significant precision in activation, which we defined as the probability that a given neuron would activate repeatedly given a prior history of activation. Eighty percent of naïve DGCs exhibited this precise firing pattern, compared to 60% of DGCs in late stage epilepsy, reflecting decreased firing precision. Additionally, we observed that as stimulus intensity increased, the amplitude of evoked calcium transients remained the same in DGCs from naïve animals. However, in late-

stage chronically epileptic animals, calcium transients were much larger, and much more variable in amplitude on average. Since calcium transient amplitude correlates with the action potential firing, DGCs in chronically epileptic mice are more likely to fire in bursts. Understanding how epilepsy alters the basic circuit properties of in hippocampal structures during the course of disease progression is important not only in targeting new therapies for seizure amelioration, but also in developing new treatments to reduce comorbidities accompanying epilepsy.

Title: Hippocampal cell loss and moderate gliosis in rats injected with bethanechol

Authors: *J. C. DA SILVA[1], J. VALERO[3], J. O MALVA[4], E. ABRÃO CAVALHEIRO[2]; [1]Disciplina de Neurologia Exptl., [2]Laboratório de Neurologia Exptl. / Dpto de Neurologia e Neurocirurgia, Escola Paulista De Medicina/Universidade Federal De São Paulo - UNIFESP, São Paulo, Brazil; [3]Ctr. for Neurosci. and Cell Biology, Univ. of Coimbra, Coimbra, Portugal; [4]Fac. Med. Univ. of Coimbra, Coimbra, Portugal

Abstract: Purpose: Cholinomimetics are widely utilized to trigger status epilepticus (SE) and brain damage induced epileptogenesis. Intrahippocampal injection of bethanechol chloride (BeCh) produces sustained acute limbic seizures and widespread brain damage in rats. However, little is known about the chronic effects of this experimental protocol. Accordingly, this work aimed at observing long-term changes following intrahippocampal BeCh in rats. Methods: Adult male Wistar rats were housed under controlled conditions with food and water ad libitum (ethic committee of UNIFESP Nº 0157/11). Using stereotaxic surgery, 30 rats were implanted with electrodes for EEG recordings and with a guide cannula directed to the right hippocampus. Seven days after surgery, 20 experimental animals were intrahippocampally injected with BeCh (300µg/2µl saline), while 10 control animals received saline. Animals were then continuously video and EEG monitored for up to 180 days. After this period, the brains of three animals of

each group were removed, frozen and sectioned for neuropathological analysis. Results: In BECh treated animals acute behavioral and electrographic changes were similar to those previously reported by our group. The long-term study allowed observing that 9 out 20 rats presented spontaneous recurrent seizures, similar to those described in the pilocarpine model of epilepsy, after a latency period of 80±32 days. These behavioral seizures were accompanied in the EEG by an initial period of fast hippocampal theta (>12 Hz) followed by spikes that quickly spread to the neocortex. Neuronal death was observed in the in the hilus and in the dentate granule cell layer. In addition, reduction in the granule cell layer thickness and moderate gliosis in CA1 could also be observed in BeCh treated rats. Conclusion: Status epilepticus induced by intrahippocampal BeCh is able to induce, in the long run, epileptic behavioral, electrographic and anatomical changes similar to those described in the pilocarpine model of epilepsy. Interestingly, less than 50 % of BeCh treated animals evolved to the chronic epilepsy in contrast to 100% observed in the pilocarpine model. Further experiments are in progress aiming at explaining these differences.

Title: Mossy fiber axon abnormalities in a conditional PTEN knock out mouse model of temporal lobe epilepsy

Authors: *C. L. LASARGE, S. C. DANZER;
Dept. of Anesthesia, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Temporal lobe epilepsy is a serious neurological disorder in which spontaneous seizures are accompanied by neuroanatomical and physiological abnormalities in the hippocampus. Dentate granule cells, which are particularly vulnerable to developing structural

abnormalities, exhibit increased mammalian target of rapamycin (mTOR) signaling in status epilepticus models of epilepsy. Recently, our lab utilized Gli1-CreER^{T2} X PTEN$^{flox/flox}$ x GFP conditional knockout mice to demonstrate that selective deletion of the phosphatase and tensin homolog (PTEN) protein, an inhibitor of mTOR, from 10-25% of granule cells was sufficient to cause epilepsy. Spontaneous seizures began 6-8 weeks after gene removal in these animals (Pun et al., *Neuron*, 2012). Deletion of PTEN from granule cells resulted in somatic hypertrophy, mossy fiber sprouting, hilar basal dendrites, and ectopic somata. In the current study, we further investigated the morphological changes in the granule cell mossy fiber axons in these animals. Mossy fiber axons of dentate granule cells project through the hilus and into CA3, where they synapse onto apical dendrites of CA3 pyramidal cells via giant mossy fiber boutons. Mossy fiber axons in the stratum lucidum had a larger diameter in the PTEN knockout mice compared to controls, and stratum lucidum was thicker in the knockout mice, with axons sprouting into stratum oriens in some animals. Interestingly, the number of giant mossy fiber boutons per length of axon was reduced in the knockout mice compared to controls. Increased axonal thickness and sprouting could support improved communication efficiency between the dentate granule cells and CA3; however, the decrease in boutons per axon length may reflect a compensatory mechanism to suppress enhanced excitatory output. Further research is necessary to delineate the timing of these structural alterations in comparison to spontaneous seizures in this mouse model, as well as the net physiological effects from the collective morphological abnormalities.

Abstract: Mice that overexpress brain-derived neurotrophic factor (BDNF) under the alpha-calcium/calmodulin-dependent protein kinase IIa promoter (termed TgBDNF mice) show an age-

dependent emergence of epileptogenesis, with spontaneous seizures developing at ~5 months. Seizures are not observed earlier, but mild cognitive deficits are evident by 2-3 months and include impairments in spatial memory. This suggests early circuit disruptions that may progress under the influence of chronically elevated BDNF to promote epileptogenesis. We have previously shown that the mossy fibres, axonal projections from the dentate gyrus granule neurons that innervate the CA3 field, are expanded in volume in TgBDNF mice compared to wildtype (WT) controls at 2-3 months of age. Present study used Golgi-Cox staining technique to visualize the hippocampal neurons with their entire dendritic projections intact within thick sections (~200μm) using 2-3 month-old TgBDNF and WT mice. A computer-interfaced image analysis system (Neurolucida, Microbrighfield, VT) is used to reconstruct dendritic arbors to assess total dendritic length, number of dendritic branches, number of spines and spine density between TgBDNF and WT mice. Analyses of granule neuron reconstructions showed that TgBDNF mice had remarkably higher total dendritic length compared to WTs (approximately X2), even though dendritic complexity in terms of the number of branches appeared to be comparable between genotypes. Similarly total number of spines was also higher in TgBDNF compared to WT granule neurons, albeit spine density did not change between genotypes. These results suggest that excess BDNF may be associated with increased synaptic input from entorhinal cortex onto granule neuron dendritic arbors as evidenced by increased dendritic length and number of spines compared to WT levels. This increase in cortical projections onto granule neurons in TgBDNF mice may be reflected in enlarged MF terminal fields as the information processing progresses in the trisynaptic circuitry. Whether the excess BDNF-related synaptic alterations include changes in the CA3 dendritic receptive fields is currently being assessed. These studies map out the early circuit disruptions in the hippocampus of the TgBDNF mice.

Title: Threshold for granule cell mediated epileptogenisis

Authors: *I. J. ROLLE[1], B. KESTLER[1], R. PUN[2], S. DANZER[2];
[1]Neurosci., Univ. of Cincinnati, Cincinnati, OH; [2]Anesthesia, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Animal and human studies of temporal lobe epilepsy have long implicated dentate granule cells (DGCs) as mediating many epileptogenic changes. Previously, we demonstrated that selective deletion of phosphatase and tensin homologue (PTEN) from 10-25% of DGCs was sufficient to produce a profound epilepsy syndrome (Pun et al., Neuron, 2012). PTEN deletion from granule cells leads to hyperactivation of the mammalian target of rapamycin (mTOR) pathway, and our PTEN knockout model reproduces abnormalities observed in temporal lobe epilepsy. These findings support the hypothesis that accumulation of abnormal granule cells may mediate temporal lobe epileptogenesis. Although abnormal granule cells are characteristic of temporal lobe epilepsy, the percentage of abnormal cells in epilepsy is often much less than 25%. To better assess the clinical significance of abnormal cells, therefore, we designed a protocol to delete PTEN from just ≈5% of DGCs. Animals were monitored 24/7 by video-EEG to quantify seizure onset and frequency. Strikingly, animals in which PTEN was deleted from ≈5% of DGCs exhibited spontaneous recurrent seizures, demonstrating that a "load" of abnormal granule cells similar to that observed in status epilepticus models of epilepsy is sufficient to generate spontaneous seizures. Interesting, the disease was less severe in mice with ≈5% PTEN KO DGC relative to animals in our previous study with 10-25% PTEN KO DGC, with later onset of seizures and reduced mortality. These findings suggest that epilepsy phenotype and disease progression may be dependent upon the number of abnormal granule cells.

Title: Selective loss of hilar mossy cells increases dentate excitability

Authors: *S. JINDE[1], V. ZSIROS[2], K. NAKAO[2], K. NAKAZAWA[2];
[1]Dept of Neuropsychiatry, The Univ. of Tokyo, Tokyo, Japan; [2]UGCB, NIMH/NIH, Bethesda, MD

Abstract: Glutamatergic hilar mossy cells of the dentate gyrus can either excite or inhibit distant granule cells, depending on whether their direct excitatory projections to granule cells or their projections to local inhibitory interneurons dominate. However, it remains controversial whether the net effect of mossy cell loss is granule cell excitation or inhibition. To explore their influence on dentate excitability and hippocampal function, we first generated a new transgenic mouse line, floxed-diphtheria toxin receptor (DTR)-line B, in which DTR is expressed under the control of the calcium/calmodulin-dependent protein kinase II (CaMKII)-alpha promoter following Cre-mediated recombination. We then crossed the line with a mossy cell/CA3 Cre line (Cre #4688) to generate double transgenic mutants in which DTR is expressed exclusively in dentate mossy cells. We have already presented in previous SfN meetings that the mutant mice, which received i.p. injections of diphtheria toxin (DT) for two consecutive days, showed selective mossy cell degeneration followed by a significant gamma-aminobutyric acid (GABA)-ergic sprouting, but not mossy fiber sprouting, in the dentate inner molecular layer (IML) by 4 weeks after treatment (chronic phase), and the impairment of pattern separation especially in first one week after treatment (acute phase). In this study, we present that the injection of toxin into this mutant induced an extensive degeneration of mossy cells throughout the longitudinal axis, accompanied by the transient increase of theta wave power of dentate local field potentials during exploration and kainic acid-induced immediate early gene expression in dentate granule cells during acute phase. By contrast, we detected no epileptiform activity or spontaneous behavioral seizures after mossy cell degeneration. These results indicate that the net effect of mossy cell excitation is to inhibit granule cell activity.

Title: Early-life seizures result in long-term elevation in anxiety in mice and spatial learning deficits

Authors: *N. AHMED[1], G. SMITH[2], E. ARBUCKLE[2], J. N. LUGO[3];
[2]Inst. of Biomed. Studies, [3]Psychology and Neurosci., [1]Baylor Univ., Waco, TX

Abstract: One of the most devastating aspects of developmental epilepsy is the long-term impact on behavior. Children with epilepsy show a high co-morbidity with psychiatric disorders. To examine whether early-life seizures result in alterations in anxiety and learning and memory we administered the chemoconvulsant kainic acid to induce seizures in C57BL/6 male mice. The mice received an injection of 2 mg/kg (intraperitoneal) of kainic acid. The treatment induced status epilepticus in postnatal day 10 pups for approximately 1.5 hrs. There was a parallel saline injected group and a naïve control group in addition to the kainic acid treated mice. The subjects were then tested in a battery of behavioral tests in adulthood: open field activity, elevated-plus maze, light-dark test, conditioned fear, novel object recognition, and Morris water maze. The mice with early-life seizures showed a consistent increase in anxiety in all three behavioral tests that measure changes in anxiety. The mice with early-life status epilepticus showed a decrease in time in the center of an open field test ($p < 0.05$) without alterations in total activity. They showed decrease time in the open arms of the plus-maze test ($p < 0.05$) and increased time in the closed arms ($p < 0.05$). The seizure mice did not show a difference in center time or in total distance traveled in the elevated plus maze compared to controls. In the light-dark test the mice with early-life seizures showed less transitions between the light to dark areas compared to the controls ($p < 0.05$). We then tested the groups in a standard fear conditioning test found no differences in freezing compared to controls. There were no differences in freezing to the conditioned stimulus (tone) or to the context. The mice with seizures also had no deficits in short-term memory in the novel-object recognition test. However, the mice with early-life seizures had a deficit in spatial learning. They had a longer latency to reach the hidden platform across the 8 trials of testing ($p < 0.01$). They also spent less time in the quadrant that originally housed the hidden platform during the probe trail ($p < 0.05$). The seizure mice appear to have alterations in anxiety and in spatial learning. We did not observe any spontaneous seizures during the testing period. These results demonstrate that mice with one insult of status epilepticus on postnatal day 10 have a long-lasting increase in anxiety and spatial learning.

Title: Lateral and medial perforant path inputs activate distinct populations of hippocampal dentate granule cells

Authors: *S. F. FRAUSTO[1,2], C. YUE[1], C. G. DENGLER[3,1], H. TAKANO[1], D. A. COULTER[1,3,4];

Abstract: The dentate gyrus (DG) is a microcircuit that is essential to the cognitive processes of the hippocampus. It has been implicated in pattern separation and pattern completion, both of which are crucial to the formation of episodic memories. Dentate granule cells (DGCs) exhibit sparse activation of distinct subsets of populations during completion of cognitive tasks *in vivo*. The principal inputs to the DG stem from the entorhinal cortex via the perforant path (PP). The PP is composed of the medial (MPP) and lateral perforant path (LPP). The medial enthorinal cortex relays spatial information through the MPP, while the lateral enthorinal cortex encodes non-spatial information. However, it is unclear how processing of information through these distinct pathways contributes to sparse activation of DGCs. In this study, we selectively activated the two components of the PP to assess their contributions to proportional activation of DGCs. We utilized in vitro multicellular calcium imaging (MCI) combined with voltage sensitive dye imaging (VSDI) techniques to examine in detail the mechanisms mediating firing specificity of DGCs in response to MPP or LPP afferent stimulation at theta frequency (5 Hz) in hippocampal entorhinal-cortex slices from adult mice (8-12 wks). We have previously reported that there is a significant overlap in DGCs activating mutually to two distinct PP stimuli, suggesting deterministic firing. We found that sparse activation of DGCs was maintained upon stimulation of PP inputs (15.2% for MPP and 25.1% for LPP, n=228 cells). Interestingly, we observed only 30% overlap in the population of DGCs that were activated mutually to MPP and LPP stimuli, with 70% of cells responding to only one input. We tested the ability of DCG-IV, a group II mGluR agonist, to selectively block the activation of PP inputs. Surprisingly, application of DGC-IV had no preferential selectivity on MPP or LPP, effectively decreasing DGC activation to both inputs (91.2% and 85.6%, respectively). DG VSDI recorded perforant path evoked EPSPs were also reduced after the application of DCG-IV. Furthermore, hilar activation was completely abolished, suggesting a loss of activation of downstream efferent structures.
In summary, we found that activation of DGCs by MPP and LPP inputs remained sparse and that the MPP and LPP activated unique DGC ensembles. These results provide insight into the

network activation properties of the normal DG and how they may contribute to cognitive functions.

Title: A novel reproducible model of neonatal stroke in mice: Comparison with a hypoxia-ischemia model

Authors: *M. TSUJI[1], M. OHSHIMA[1], A. TAGUCHI[2], Y. KASAHARA[2], T. IKEDA[3], T. MATSUYAMA[4];

Science, Hyogo Col. of Med., Nishinomiya, Japan

Abstract: Background & Objectives: Neonatal stroke occurs in 1/4000 live births and leaves life-long neurological impairments, such as cerebral palsy. Currently, the rodent models of neonatal stroke that are available exhibit significant inter-animal variability, which makes it difficult to accurately assess the mechanisms of brain injury and the efficacy of candidate treatments. We aimed to introduce a novel, highly reproducible model of stroke, middle cerebral artery occlusion (MCAO), in immature mice, and to evaluate the reproducibility of this model compared with a conventional hypoxia-ischemia (HI) model.
Methods: Postnatal day 12 (P12) male and female CB-17 mouse pups were prepared for surgery. Permanent MCAO was produced by directly electrocauterizing the left MCA. HI was induced by a combination of permanent occlusion of the left common carotid artery and systemic hypoxia. The cortical surface cerebral blood flow (CBF) was measured by a laser speckle flowmetry imaging system. Animal behaviors were evaluated using the rotarod test and the open-field test. Morphological evaluation of the brain injury was performed at 48 hours after the insult using

TTC staining, and at 8 weeks after the insult using the H&E staining.
Results: The MCAO model exhibited excellent long-term survival; 85% up to 8 weeks after the insult. Infarct was evident in every animal with MCAO (n = 27) and was confined to the cortex, with the exception of some mild thalamic injury. While the % stroke volume 48h after the insult was consistent in the MCAO group, range: 17.8-30.4% (minimum-maximum), it was substantially less consistent in the HI group, range: 3.0-70.1%. This contrasting variability between the two models was also evident in the CBF, 24h after the insult, and in the ipsilateral hemispheric volume, as assessed at 8 weeks after the insult. Mice with MCAO exhibited significant neurofunctional deficits in the rotarod and open-field tests.
Conclusions: Preclinical studies for neonatal stroke could become more reliable using this model, with even a potential reduction in the number of pups required for statistical significance. The contrasting variability between the two models may provide insights into the factors that contribute to inter-animal variability in brain injury.

Title: A critical role for cortical activation in protection from ischemic stroke damage

Authors: *M. F. DAVIS, C. H. CHEN-BEE, R. D. FROSTIG;
Neurobio. & Behavior, UC Irvine, IRVINE, CA

Abstract: Our lab has previously demonstrated that complete protection from impending ischemic stroke damage can be achieved if single whisker stimulation is delivered within the first 2 hours following ischemic onset in a rodent model of permanent middle cerebral artery occlusion (pMCAO). Reperfusion was achieved via stimulation induced collateral vessel flow into MCA branches. Given that animal and clinical research suggest that reperfusion alone does not necessarily result in complete protection from ischemia, we hypothesized that evoked cortical activity (resulting from sensory stimulation) might play role, in addition to initiating

blood flow return, in achieving more effective protection from impending stroke damage. In the current study we sought to separate the variables of reperfusion and cortical activity by using a removable artery clamp to temporarily occlude middle cerebral artery (MCA) for one hour (1h tMCAO). In this way we ensured that equivalent reperfusion occurred in both experimental and un-stimulated control animals at the same post-occlusion time point and could assess the effect of adding sensory stimulation evoked cortical activity. We assessed blood flow using laser speckle imaging throughout the experiment and stained for subsequent infarct using TTC in stimulated (1h tMCAO with stim; n=17) and un-stimulated (1h tMCAO NO stim; n=12) animals. We demonstrate that blood flow drop, reperfusion level, and blood flow the following day is identical between groups. Despite identical reperfusion between groups, the addition of single whisker stimulation evoked cortical activity significantly reduced damage in stimulated compared to un-stimulated animals (1h tMCAO with stim: mean = 12.5+1.9mm3 vs 1h tMCAO NO stim: mean = 24.0+3.9mm3; paired t-test $t(29)= 3.71$; $p< 0.0009$). Further analysis suggests that evoking cortical activity within the ischemic cortical region might temper the damaging ability of reperfusion. In 1h tMCAO NO stim control animals, increased reperfusion values following clamp release were correlated with increased infarct size (Pearson's correlation [two tailed] [$r = 0.633$, $n =12$, $p<0.05$]), whereas in 1h tMCAO with stim animals, increased reperfusion values were not correlated with increased infarct size and in fact there was a trend towards increased reperfusion values being correlated with decreased infarct sizes. If translational, stimulation based treatment could provide a means to augment current blood flow re-establishment strategies and perhaps lead to outcomes more similar to the complete protection observed in our rodent pMCAO model.

Title: Investigating the association between reduced CVR, cortical thinning and cognitive deficits in the pediatric population with sickle cell disease

Authors: *J. KIM[1,3], J. LEUNG[3], J. LERCH[4], G. DEVEBER[4], B. NIEMAN*[4], A. KASSNER[3,2];

[2]Med. Imaging, [1]Univ. of Toronto, Toronto, ON, Canada; [3]Physiol. and Exptl. Med., [4]Hosp. For Sick Children, Toronto, ON, Canada

Abstract: Background: Sickle cell disease (SCD) is a genetic disorder that is known to affect normal physiological and neurological development. Children with SCD suffer from cognitive deficits even with brains that are assessed as normal with conventional Magnetic Resonance Imaging (MRI). Cerebrovascular reactivity (CVR), defined as the percent change in cerebral blood flow in response to a CO_2 stimulus, is determined with the use of blood-oxygen level-dependent (BOLD) MRI sequence. CVR can be utilized to gauge cerebrovascular health and therefore CVR can aid with the clinical assessment of SCD patients. In non SCD patients, brain regions with reduced CVR have previously been correlated to cortical thinning. However, it is unknown whether compromised CVR in SCD has a direct physiological impact on cortical integrity and could serve as a biomarker of cognitive decline.
Objective: The purpose of this study was to assess if reduced CVR is associated with cortical thinning in children with SCD.
Patients and Methods: 40 SCD patients (12-18 years) and 15 controls were imaged on a 3T MRI. Anatomical and CVR data were acquired. For CVR, a BOLD sequence was used during a computer-controlled CO_2 stimulus. CVR maps were computed by correlating the voxel-wise BOLD signal changes to the end-tidal CO_2 waveform, then coregistered to the anatomical space. Cortical thickness was computed from the anatomical data using the CIVET pipeline and a correlation analysis between thickness and CVR was performed within each functional region of the brain using the MATLAB based toolkit SurfStat.
Result: Group analysis between patients and controls revealed multiple regions with significant reduction in both cortical thickness and CVR in SCD patients. Some highlighted correlations included strong correlations in the right post central gyrus ($r = 0.5996$), moderate to significant correlation in the right orbital frontal cortex ($r = 0.5328$) and moderate correlations in the bilateral cuneus ($r = 0.4311$ left, $r = 0.4038$ right).
Discussion: In this study, we have demonstrated a linear relation between the degree of cortical thinning and reduced CVR in specific regions of the brain within the pediatric SCD population. This finding can potentially indicate that certain cortical areas are increasingly susceptible to disruptions in normal blood flow regulation leading to poor maintenance of the structural integrity in these areas. Future objectives will include measures of cognitive ability, which will be correlated with CVR and cortical thickness data in order to investigate the relationship between cognitive deficits, CVR and cortical thinning.

Title: Role for microRNA-200c in response to ischemia

Authors: C. M. STARY, L. XU, Y.-B. OUYANG, J.-M. MOON, *R. G. GIFFARD;
Stanford University, Dept. of Anesthesia, Stanford, CA

Abstract: Micro-RNAs (miRs) are small non-coding RNAs that inhibit the translation of target mRNAs. Homology sequence searches suggest miR-200c may target genes that regulate cell survival. We hypothesized that miR-200c is a determinant of survival following cerebral ischemia by modulating the cellular response to ischemia. We investigated its effect on in vitro ischemic injury, and whether expression of miR-200c changed in response to focal ischemia. Candidate pro-survival genes (GRP78 and BCL2) were identified using Targetscan.org. For in vitro experiments, mouse neuronal and astrocyte cultures were transfected with miR-200c mimic or inhibitor and subjected to oxygen-glucose deprivation, followed by 24 hrs reperfusion. Levels of miR-200c were assessed by RT-qPCR and GRP78 and BCL2 protein levels by western blot. Cell death was assessed by lactate dehydrogenase release. Baseline levels of miR-200c in naïve astrocyte and neuronal cultures were comparable. Treatment with miR-200c mimic and inhibitor effectively increased and decreased miR-200c levels respectively in cell culture. Astrocytes treated with miR-200c inhibitor exhibited greater Grp78 and Bcl2 protein levels. When stressed by oxygen-glucose deprivation, pretreatment with inhibitor improved astrocyte cell survival. Treatment of neuronal cultures with miR-200c mimic exacerbated cell death. For in vivo experiments, adult male C57B6 mice were subjected to 1 hr MCAO and 1 hr reperfusion, followed by assessment of miR-200c levels. In brains of mice subjected to MCAO, miR-200c increased several fold. The results of this study demonstrate that the use of mimic and inhibitor alters levels of miR-200c, and levels of Grp78 and Bcl2 protein. This results in increased injury in vitro with mimic, and decreased injury with inhibitor. Further, miR-200c increases in response to focal ischemia. These findings suggest that the increase in miR-200c that accompanies cerebral ischemia may exacerbate brain injury by reducing levels of cell-survival proteins Grp78 and Bcl2. This suggests targeting miR-200 could be a future therapeutic candidate for stroke.

Title: Erythropoietin attenuates KCC2 chloride cotransporter loss and promotes recovery following *In utero* hypoxia-ischemia

Authors: *L. L. JANTZIE[1], D. J. FIRL[2], S. ROBINSON[2];
[1]Neurol., [2]Neurosurg., Children's Hosp. Boston, Boston, MA

Abstract: Children with perinatal brain injury are prone to neuropsychiatric disabilities including cognitive disorders, learning disabilities, autism and epilepsy. During development, the potassium chloride co-transporter KCC2 is upregulated and directs the formation of essential inhibitory circuits by driving $GABA_A$ receptor activation to hyperpolarization. Loss of KCC2 is observed in preterm infants with brain injury and resected epilepsy tissue. Here, we investigated how late gestation hypoxia-ischemia alters KCC2 upregulation and impairs the formation of essential inhibitory circuits. We hypothesized that KCC2 would be chronically decreased following prenatal brain injury via calpain-dependent mechanisms and that postnatal treatment with erythropoietin (EPO) would protect the developing brain and reverse KCC2 loss. Accordingly, prenatal *in utero* transient systemic hypoxia-ischemia (TSHI) was performed on embryonic day 18 (E18) rats to mimic brain injury in infants born extremely preterm. Following TSHI, EPO or vehicle was administered from postnatal day P1-5 (2000 IU/kg/dose/ip). KCC2 mRNA and protein were assessed in microdissected CA3 from P2-P28 ($n \geq 8$/group for all). After TSHI, functional oligomeric KCC2 was reduced by 13% compared to sham (0.87±0.034 vs. 1.01±0.0.03, $p<0.001$). Loss of oligomeric KCC2 persisted through P28, with TSHI KCC2 expression 18% below shams (0.82±0.03 vs. 1.01±0.05, $p=0.002$). Along with this loss in KCC2, TSHI significantly increased 90 and 30 kD KCC2 fragmentation at P11 and μ-calpain activity by 59%, as measured by the ratio of cleaved to full length αII-spectrin (1.59±0.11 vs.1.00 ±0.04, $p=0.005$). Neonatal EPO treatment normalized KCC2 oligomer levels at P11 (1.11±0.06, two-way ANOVA $p<0.001$) and P28 (0.995±0.03) suggesting early neonatal EPO treatment restores

KCC2 oligomer levels in young adult brains. EPO also decreased the αII-spectrin ratio following TSHI by 44% (p=0.01). In sum, prenatal brain injury limits the developmental increase of KCC2 protein expression. Moreover, postnatal administration of EPO reverses KCC2 loss through P28, attenuates KCC2 oligomeric fragmentation and normalizes μ-calpain activity following TSHI. These data indicate it is possible to reverse abnormalities in inhibitory circuit development in the postnatal period. KCC2 loss may be essential to the molecular pathophysiology of late gestation brain insults, and EPO treatment is a viable and clinically relevant therapeutic strategy in this patient population.

Title: Neuroprotective effects of Taurine and S-methyl-N, N diethylthiocarbamate sulfoxide on rat middle cerebral artery occlusion stroke model

Authors: *P. MOHAMMAD GHARIBANI, J. MODI, J. MENZI, H. PRENTICE, J.-Y. WU; Florida Atlantic Univ., Boca Raton, FL

Abstract: Taurine has been shown to provide protection against neurological diseases, such as Huntington's and stroke. On the other hand, we have shown in our previous study that either taurine (40 mg/kg) or S-methyl-N, Ndiethylthiocarbamate sulfoxide (DETC-MeSO) (5.6 mg/kg) could attenuate glutamate excitotoxicity and protect against Endoplasmic Reticulum (ER) stress in the model of Middle Cerebral Artery Occlusion (MCAO). In this study, we employed combination of taurine and DETC-MeSO with a lower dose (0.56 mg/kg) for in vivo model of rat MCAO. Using taurine greatly decreased the infarct area and levels of the ER stress proteins p-IRE-1 and cleaved ATF6. On the other hand, taurine induced an up-regulation of the Bcl-2/Bax ratio and downregulation of Caspase-3 protein activity. DETC-MeSO in a lower dose almost did not show any changes on ER stress. In contrast, when it was administered with the combination of taurine, not only reduced infarct size significantly less than administering taurine individually but also it decreased αII-spectrin cleavage and the level of ATF4 protein expression in PERK pathway. Our results show not only taurine elicits neuroprotection through the

activation of the ATF6 and the IRE1 pathways, but also in combination with DETC-MeSO with lower dose can inhibit all 3 pathways of ER stress besides apoptosis.

Title: Regional and gender specific hypothermic neuroprotection in a neonatal mouse model of hypoxic-ischemic injury

Authors: J. C. BURNSED[1], J. ZHANG[2], R. CHAVEZ-VALDEZ[1], K. KESAVAN[1], L. J. MARTIN[3], *F. J. NORTHINGTON[1];
[1]Pediatrics and Neonatalogy, [2]Radiology and Neuroimaging, [3]Pathology and Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Background: Hypothermia (HT) is standard treatment for infants with moderate to severe hypoxic ischemic injury (HI); however, HT is not completely protective. Additionally, there is well described regional vulnerability to injury in the immature brain and gender biased differences in susceptibility to injury and response to therapy (Hill 2011). Studies examining MRI of infants receiving HT or normothermia suggest that HT may have differential regional protection (Inder 2004, Rutherford 2005, Bonafacio 2011). There is not a well established neonatal murine model of HT following neonatal HI. Objectives:To develop a reproducible model of HT in neonatal mouse model of HI, determine whether HT provides regional and gender specific patterns of neuroprotection. Design/Methods: HI was created in postnatal day 10 (p10) C57BL6 mice using the Vannucci model (unilateral carotid ligation+45 minutes FiO2=0.08). Mice were randomized to HT (31ºC) or normothermia (36ºC) for 4 hours immediately following HI. T2-weighted MRI was obtained on one cohort of mice at p11 and p18. Regions of interest (cortex, thalamus, striatum, and hippocampus), total lesion and brain volumes were measured on T2-weighted images. Fresh tissue from another cohort of mice was obtained at p11 for protein activity assay of complex I and caspase 3 and Western blot for

nitrotyrosine. Data were analyzed using a Mann-Whitney U test and one-way ANOVA. Results: Total injury volume in males was significantly decreased at p18 in the hypothermia group on T2-weighted images (Mann Whitney U Test: p=0.05). In males, HI appears to impair brain growth from p11 to p18, this effect appears to be reversed by 4 hours of 31°C hypothermia (One-way ANOVA, p=0.002;post-hoc (Tamhane), p=0.04 (control vs. normothermia), p=0.006 (normothermia vs. HT)). Regional injury volumes in males show significant neuroprotection at p18 in cortex and hippocampus (Mann Whitney U Test: p=0.05 (n=3) p=0.006 (normothermia vs. HT)). Caspase-3 activity (One-way ANOVA, p=0.012; p=0.01 vs. control; p=0.05 vs. normothermia (Tukey post-hoc test) and nitrotyrosine labeling is increased and complex I activity is decreased **(**One-way ANOVA, p=0.04, p=0.05 vs. hypothermia (Tukey post-hoc test), in forebrain of normothermic animals compared to hypothermia and control groups. Conclusions: Hypothermia following HI provides measureable regional neuroprotection and prevents evolution of injury from 1-7 days in p10 male mice. Hypothermia in males may provide specific mitochondrial protection. Whether the same is true in females and studies to determine whether these early findings impact on long term structural and functional outcomes is underway.

Title: The initial inflammatory response may predict long-term functional outcome in stroke

Authors: *B. STAMOVA[1], G. JICKLING[1], B. ANDER[1], X. ZHAN[1], D. LIU[1], J. KHOURY[2], A. PANCIOLI[3], E. JAUCH[4], J. P. BRODERICK[3], F. R. SHARP[1];

Biostatistics and Epidemiology, Cincinnati Children's Hosp. Med. Center,, Cincinnati, OH; [3]Neurol., Univ. of Cincinnati, Cincinnati, OH; [4]Div. of Emergency Med., Med. Univ. of South Carolina, Charleston, SC

Abstract: BACKGROUND AND PURPOSE:
The immune and clotting systems play a major role in causing stroke and affecting outcomes. Leukocytes detect blood clots in the vascular system, damaged brain endothelium, atherosclerotic plaque and platelets adhering to vessel walls, and leukocytes modulate clotting. This study aimed to (1) develop a pilot profile of genes, whose early post-stroke expression associates with late (5-day and 90-day) functional outcome; and (2) identify the early inflammatory pathways involved in long-term functional outcome in stroke.
METHODS:
Subjects with ischemic stroke (IS) from the CLEAR trial (NCT00250991) were analyzed (65.8+/-13.5 years). A Derivation Set of patients with IS (n=35 and n=26 for 5-day and 90-day outcome, respectively), and a Validation Set (n=15 and n=11 for 5-day and 90-day outcome, respectively) were evaluated for late stroke outcome prediction. Whole blood was drawn ≤3 hours after stroke onset (no treatment) and RNA processed on whole genome microarrays. Pearson correlations between gene expression and NIH Stroke Scale (NIHSS) at 5 days and 90 days, after adjusting for batch, age and biological sex, were determined. Genes from the top 20 positive and the top 20 negative correlations (FDR<0.001, |r>0.9|) in the Derivation Set were used to generate a Support Vector Machine Regression model, which was tested on the Validation Set.
RESULTS:
The top 40 genes identified to correlate the strongest with 5-day and 90-day NIHSS predicted outcome in the Validation set with R^2=0.98 and 0.96, respectively. There was no overlap of the 5-day and 90-day predictor genes. The top pathways over-represented in the top 200 genes (FDR p<0.001, |r|>0.7), whose expression correlates with 5-day outcome was sphingosine-1-phosphate signaling (FDR p=0.002), implicated in stroke and progression of disease. The top 90-day pathway was Integrin Signaling (FDR p=0.2), implicated in stroke risk and in functional outcomes following stroke. Predicted upstream activation of TGFB1, TGFB3, AGT (Angiotensinogen), and VEGF growth factors, and inhibition of ABCB2 transporter and hypoxia-inducible factor1 alpha (HIF1a) expression at 3h, correlated with 90-day outcome. Several of these have been shown to affect stroke outcome in animal models and humans.
CONCLUSIONS:
This pilot study adds to the evidence that the immune response after stroke may influence later functional outcome. It will expand our understanding of the genomic underpinnings associated with stroke outcome. These findings need to be validated in a larger sample and in an independent cohort. Additional studies associating gene expression with infarct volume and outcome sub-scales is underway.

Title: Possible relationship between decreased expression of lysosomal-associated membrane protein type 2A and delayed neuronal death after brain ischemia

Authors: *E. DOHI[1,2], S. TANAKA[1,2], T. SEKI[2], T. MIYAGI[2], I. HIDE[2], T. TAKAHASHI[1], M. MATSUMOTO[1], N. SAKAI[2];
[1]Neurosci. and Theraputics, [2]Mol. and Pharmacol. Neurosci., Hiroshima Univ., Hiroshima, Japan

Abstract: Autophagy is a conserved mechanism responsible for the continuous clearance of unnecessary organelles or misfolded proteins in lysosomes. Three types of autophagy have been reported in the difference of substrate delivery to lysosome: macroautophagy (MA), microautophagy, and chaperone-mediated autophagy (CMA). Among these types, CMA is a unique autophagy system that selectively degrades substrates detected by heat shock cognate protein 70 (HSC70). Substrates are then transferred to the lysosomal membrane through an interaction with lysosomal-associated membrane protein type 2A (LAMP-2A), thereby translocated into the lysosome. Recently, we have reported that CMA is activated during hypoxia and contributes to the survival of cells under these conditions (Dohi E et al., Neurochem Int. 2012). In the current study, we asked whether CMA would be activated in neurons after brain ischemia in vivo. Male Wistar rats, 7 weeks of age, were subjected to permanent middle cerebral artery occlusion (pMCAO) and LAMP-2A expression after cerebral ischemia was evaluated by both westernblotting and immunohistochemistry. LAMP-2A expression in the lysosomal fraction was decreased at day 2, compared with that in sham control, and then it was increased until day 7

in the ipsilateral hemisphere. In the contralateral hemisphere, LAMP-2A expression in the lysosomal fraction was slightly increased at day 4 and then returned to the basal level at day 7. Besides, the LAMP-2A staining in the ischemic brain revealed that LAMP-2A expression in neurons was decreased in the ischemic hemisphere from 1 day to 2 days after pMCAO. However, at 7 days after pMCAO, cortical neurons in the peri-infarct area indicated stronger LAMP-2A expression, compared with the contra-lateral side. We further evaluated LAMP-2A expression using the rat four-vessel occlusion (4VO) model (Pulsinelli et al., 1982). LAMP-2A expression was decreased mainly in the vulnerable CA1 neurons of hippocampus 2 days after ischemia. These results suggested that hampered CMA activity in the ischemic vulnerable neurons might be associated with delayed neuronal death after brain ischemia.

Title: Effects of focal ischemic lesions of the prefrontal cortex on cognition in the rat

Authors: *R. A. DÉZIEL, R. A. TASKER;
Univ. of Prince Edward Island, Charlottetown, PE, Canada

Abstract: Stroke is the most common cause of long-term disability in adults, and it has been estimated that approximately 30% of stroke survivors experience cognitive impairments persisting for at least three months post-stroke. As well, approximately half of all cases of dementia may be wholly or in part due to vascular impairment. Many cognitive deficits in stroke survivors occur because of damage to the prefrontal cortex (PFC), which has been heavily implicated as the seat of executive function in the brain. There is a need, therefore, for an improved understanding of the role of the PFC in executive function deficits, as well as the role of neuroplasticity in cognitive recovery. Currently, there are few rat models examining prefrontal

cognitive dysfunction following stroke and none that utilize focal ischemic lesions specifically in the PFC. Utilizing bilateral microinjections (1 ul) of the vasoconstricting peptide endothelin-1 (ET-1) (400 pmol) into the medial PFC in adult male SD rats (N=12/group) we produced highly localized ischemic lesions in the PFC (or sham) and the effects of these lesions on cognition were assessed using a test of temporal order memory and a colour-texture discrimination attentional set-shifting task. Following testing rats were euthanized and lesion location and volume was confirmed histologically. The combination of focal damage to a specialized cortical region and behavioural tests of executive function shows potential for developing a model of post-ischemic cognitive dysfunction that will support subsequent studies of cognitive rehabilitation and cortical neuroplasticity.

Title: TRPM2 contributes to ischemia-induced delayed neuronal death in hippocampal CA1 region and impairment in motor activity via disrupting zinc homeostasis

Authors: *M. YE[1], W. YANG[1], W.-Y. YU[1], X.-H. ZHANG[1], L.-H. JIANG[2], J.-H. LUO[1]; [1]Dept. of Neurobio., Inst. of Neuroscience, Zhejiang Univ. Sch. of Med., Zhejiang Province, China; [2]Sch. of Biomed. Sciences, Fac. of Biol. Sciences, Univ. of Leeds, Leeds LS2 9JT, United Kingdom

Abstract: Oxidative stress (OS) is a major factor in ischemia-induced neurological damage.TRPM2 is a nonselective cation melastatin-related transient receptor potential channel activated by reactive oxygen species (ROS), and is highly expressed in the brain. Here we investigated the role of TRPM2 in transient ischemia induced delayed neuronal death in hippocampal CA1 region using wild-type and TRPM2 knock-out mice that were subjected to

transient global ischemia by bilateral common carotid arteries occlusion (BCCAO) treatment for 15 min followed by reperfusion for 72 hours. There was substantial delayed pyramidal neuronal death in the wild-type mice, which was significantly reduced in the TRPM2 KO mice. Transient global ischemia impaired motor activity in the wild-type mice, but such impairment was significantly attenuated in the TRPM2 KO mice. Disruption in zinc homeostasis has been strongly involved in OS-induced neuronal death. Parallel using confocal or two-photon microscopy experiments showed that ischemia or H2O2 significantly elevated the cytosolic zinc levels in CA1 pyramidal neurons relatively to untreated neurons which isolated from the wild-type mice. Such an ischemia induced elevation in the cytosolic zinc levels was almost completely abolished in TRPM2 deficient neurons. In summary, our results provide defining evidence to support that TRPM2 plays a significant role in ischemia-induced delayed neuronal death and impairment in motor function activity and also suggest that TRPM2-mediated disruption in zinc homeostasis may act as a novel mechanism responsible for ischemia induced neurological damage.

Title: A novel method for inducing focal ischemia in the rat using L-N5-(1-Iminoethyl)ornithine

Authors: *A. VAN SLOOTEN[1], A. CLARKSON[2], B. CONNOR[1];
[1]Dept Pharmacol. & Clin. Pharmacology. Ctr. for Brain Res., The Univ. of Auckland, Auckland, New Zealand; [2]Depts of Anat. & Psychology, Brain Hlth. Res. Ctr., Univ. of Otago, Dunedin, New Zealand

Abstract: Stroke is a devastating neurological disorder for which new therapies are urgently needed. Animal models of stroke are a vital step in developing these treatment strategies. The middle cerebral artery occlusion (MCAo) model in rats can be highly variable and has associated mortality. We therefore sought to establish an alternative, high-throughput rat model of focal ischemia to investigate inflammation and repair in subcortical infarcts. Injection of L-N5-(1-Iminoethyl)ornithine (L-NIO), an endothelial nitric oxide synthase (eNOS) inhibitor, into the brain causes vasoconstriction and resultant ischemia. The aim of this study was to characterise the infarct, neuroinflammatory response and motor function impairments following L-NIO-induced ischemia. Male Sprague Dawley rats (300-350g) underwent right jugular vein ligation followed by L-NIO injection directly into the striatum (2µmol L-NIO in 5µl saline). Sham animals received saline injections. To assess inflammatory responses, animals were euthanized 3, 7, 14 or 35 days following L-NIO or saline injections (n=3-9/group) and immunohistochemistry performed on fixed tissue. Motor function was assessed using the cylinder test at baseline, 1 and 4 weeks post-surgery (n=7-9/group). L-NIO injection produced a consistent infarct limited to the striatum with no mortality. Although the infarct volume did not change significantly over time, atrophy of the ipsilateral striatum was observed at 35 days post-insult compared to sham ($P<0.05$). Iba1 and GFAP immunoreactivity were elevated for 35 days following L-NIO injection compared to sham surgery ($P<0.05$), demonstrating that L-NIO-induced ischemia results in microglial infiltration and initiation of reactive astrogliosis respectively. GFAP immunoreactivity was maximal 7 days following ischemia, consistent with an evolving astroglial response observed in this model. Fluoro-jade C was present within the lesion 3-7 days post-insult indicating ongoing cell death. In addition, L-NIO-induced focal ischemia resulted in impaired forelimb use on the cylinder test both 1 and 4 weeks post-insult compared to controls ($P<0.05$). We have characterised a novel method of inducing focal ischemia in rats using the eNOS inhibitor L-NIO. This model results in ongoing neuroinflammation and impaired motor function following the insult. We propose that L-NIO injection provides a consistent and high-throughput approach to model focal ischemia and future studies using this model will allow us to assess anti-inflammatory approaches to improve stroke outcomes.

Title: Mitochondria play a role in the protective and destructive effects of chronic intermittent hypoxia on the ischemic brain

Authors: *K. A. JACKMAN, P. ZHOU, G. FARACO, T. KAHLES, C. COLEMAN, V. M. PICKEL, C. IADECOLA;
Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY

Abstract: Severe obstructive sleep apnea, resulting in chronic intermittent hypoxia (CIH), is an independent risk factor for stroke and dementia (New Engl J Med 353(19) 2005), but the mechanisms are unknown. We have shown that mice subjected to 35 days CIH have marked dysfunction in the regulation of the cerebral circulation (Hypertens 60(1) 2011). In addition, studies in the developing brain suggest that CIH alters mitochondrial function (AJP Cell Physiol 298(6) 2010). Thus, CIH could increase stroke risk by impairing cerebral perfusion and/or mitochondria. Conversely, exposure to CIH has been reported to render the brain tolerant to ischemia (Ann Neurol 69(6) 2011). Therefore, the effects of CIH on the post-ischemic brain can be either protective or destructive, but the factors responsible for such dichotomy are undefined. We hypothesized that the severity of hypoxia during CIH is critical in determining the susceptibility of the brain to ischemic injury. Male C57BL6 mice underwent CIH (90 sec hypoxia-90 sec room air; 8 h/day during sleep) with 5% or 10% O_2 for 35 days (J Neurosci 30(36) 2010). Sham mice received room air according to the same schedule. First, we examined the effect of CIH on mitochondrial resistance to depolarization using Ca^{2+} induced depolarization of transmembrane potential ($\Delta\Psi m$). Brain mitochondria isolated from mice exposed to CIH with 10% O_2 were less susceptible to Ca^{2+} induced loss of $\Delta\Psi m$ (Ca^{2+} conc. inducing $\Delta\Psi m$ loss: Sham 4.6±0.2; CIH 5.7±0.2 nmol/mg protein; $P<0.05$; n=9), indicative of increased resistance to depolarization. In contrast, mitochondria from mice exposed to more severe CIH (5% O_2) had increased susceptibility to Ca^{2+} induced $\Delta\Psi m$ loss (Sham 5.0±0.4; CIH 2.9±0.2 nmol/mg protein; $P<0.05$; n=9). In agreement with these opposing effects on mitochondria, mice exposed to CIH with 10% O_2 were protected from brain injury produced by transient middle cerebral artery occlusion (infarct volume at 72 h: Sham 34±5; CIH 18±2 mm^3; $P<0.05$; n=10/8), while mice exposed to more severe CIH (5% O_2) had significantly larger infarcts (Sham 25±5; CIH 46±7 mm^3; $P<0.05$; n=8/10) and motor impairment (hanging wire test: Sham 24±8; CIH 7±1 sec; $P<0.05$; n=8/9). The data suggest that CIH with 10% O_2 protects the brain from cerebral ischemia, an effect associated with increased mitochondrial resistance to Ca^{2+} induced depolarization, while CIH with 5% O_2 renders mitochondria more susceptible to depolarization and the brain more vulnerable to ischemia. We conclude that the effects of CIH on ischemic brain injury are dichotomous. The greater vulnerability to ischemia induced by more severe CIH may underlie the increased stroke risk in patients with severe sleep apnea.

Title: Selective neuronal vulnerability of hippocampal CA1 neurones in acute neurological disorders

Authors: *T. BARTSCH[1], J. DÖHRING[1], H. BRAUER[1], J. LAGIES[1], A. ROHR[2], G. DEUSCHL[1], O. JANSEN[2];
[1]Dept. of Neurol., Univ. of Kiel, Univ. Hosp., Kiel, Germany; [2]Univ. Hosp. Schleswig-Holstein, Inst. of Neuroradiology, Kiel, Germany

Abstract: The CA1 region of hippocampus is critically involved in memory processing and learning but is also selectively vulnerable to a variety of metabolic and excitotoxic insults which can be most prominently seen in acute neurological conditions such as hypoxia-ischaemia, hypoglycaemia, encephalitis and epilepsy. The basis of this regional susceptibility is, however, poorly understood may include high demand for energy metabolism and consequent formation of reactive oxygen species in vulnerable neurons. The clinical correlates of hippocampal affection, their temporal course and sequelae have only recently been studied in vivo using magnetic resonance imaging (MRI). Here, the cellular and imaging correlates and pattern of hippocampal damage was analysed by studying the evolution of hippocampal CA1 diffusion and ADC changes in acute neurological disorders. In patients with hippocampal ischaemia (n=50), limbic encephalitis (n=30), after status epilepticus (n=17) and transient global amnesia (n=53), CA1 neurones exhibited a particular susceptibility to metabolic stress, irrespective of the nature of the insult. The evolution of diffusion changes over the course of the disease show that CA1 diffusion lesions can be most prominently detected within the first three days after the insult. Hypoxic-ischaemic insults lead to a significant lower rADC suggesting that the ischemic insult results in a stronger impairment of cellular metabolism. Studying the imaging correlates of hippocampal affection provides valuable insight into the pathophysiology and neurobiology of the hippocampus.

Title: Hsp70, hsp90 and icam-1 as early biomarkers for global cerebral ischemia

Authors: *M. JIANG[1], E. CURFMAN[1], B. C. HONG-GOKA[1,2], R. D. SWEAZEY[1], F.-L. F. CHANG[1];
[1]Med. Educ., Indiana Univ. Sch. of Medicine-Fort Wayne, Fort Wayne, IN; [2]UCSF-Fresno Alzheimer's & Memory Ctr., Fresno, CA

Abstract: Global cerebral ischemia caused by cardiac arrest often leads to severe brain damage, and reperfusion may further injure the brain. Currently, the only treatment to protect the brain following global ischemia is hypothermia, which has limited efficacy. Most published animal studies of global ischemia have focused on molecular events at least one day after the start of reperfusion. This leaves an information gap at earlier time points where significant damage occurs. Identification of early ischemic damage biomarkers that can be used to address this information gap is important for the development and assessment of future neuroprotective treatments. Using a global ischemia model, we have previously demonstrated increased expression of Hsp70 and ICAM-1 following 6min occlusion/3h reperfusion. Here we report results of extending ischemia and reperfusion times.
This study is in compliance with NIH animal care guidelines and was approved by the Purdue University Animal Care and Use Committee. We used a modified 4-vessel occlusion (4-VO) model in isoflurane anesthetized rats. Briefly, both vertebral arteries were exposed and electro-cauterized and the common carotid arteries were isolated and clamped for either 6 or 12min followed by 3 or 6h reperfusion. Sham animals were subjected to the same procedures except the arteries were not occluded. Cerebral blood flow and other physiological parameters were monitored. At the conclusion of the experiment, rats were sacrificed and alternate sections of brain were stored in RNAlater or immersion fixed in buffered formalin.
H&E and silver-cresyl violet double staining confirmed previous findings of damage in the

hippocampus as early as 3h of reperfusion. Similarly, mRNA and protein levels of Hsp70 and ICAM-1 were up-regulated in all stroke groups. This increase was higher in 12min/6h compared to 6min/3h or 6min/6h reperfusion groups, suggesting brain damage was mainly due to ischemia, not reperfusion, in this model. Hsp90 protein in the 6min/3h group was unchanged, but decreased in 6min/6h and 12min/6h reperfusion groups. The decrease in Hsp90 protein expression was not mirrored by mRNA levels which remained stable in all groups. The mechanism of reversed expression patterns of Hsp70 and Hsp90 need further study.
The time-dependent expression of Hsp70, Hsp90 and ICAM-1 indicates cells at risk of damage following global ischemia. Besides providing insights into the molecular events of global ischemia at these early time points, these proteins could potentially be used as biomarkers to assess drug treatment effects in our 4 VO model.

Title: Activation of HIF-1 mediates exacerbated blood-brain barrier disruption in ischemic stroke

Authors: *Z. ZHANG, H. SHI;
Univ. of Kansas, Lawrence, KS

Abstract: Hyperglycemia is associated with worsened outcomes in acute ischemic stroke. Accumulating evidence indicates that the worsened outcomes may be due to high glucose-induced cerebral vascular complications, especially disruption of the blood-brain barrier (BBB). Increased BBB permeability may contribute to the development of neurological damage in stroke. We hypothesize activation of hypoxia inducible factor-1 (HIF-1) and its target gene vascular endothelial growth factor (VEGF) is involved in hyperglycemia-aggravated BBB disruption during ischemia/reperfusion.
C57/6J mice were rendered diabetic with STZ injection. Diabetic mice and non-diabetic mice

(control) were subjected to 90 min transient middle cerebral artery occlusion (MCAO) and 24 h reperfusion. We found that there was a higher expression of HIF-1α and its target gene VEGF after MCAO/reperfusion in brain microvessels in diabetic mice than those in control animals. At the meantime, diabetic mice demonstrated exacerbated BBB damage and tight junction disruption in the ipsilateral hemisphere of the ischemic brain. Hyperglycemia also increased brain infarction and neurological deficits. Furthermore, normalizing the level of blood glucose by insulin injection abolished HIF-1α upregulation in diabetic mice and reduced the level of brain infarction back to that of control animal. Moreover, endothelial-specific HIF-1α knock-out mice were utilized to identify HIF-1's specific role in BBB disruption. HIF-1 inhibition ameliorated brain infarction and edema formation in diabetic animals after MCAO/reperfusion.
These results strongly indicate that HIF-1 plays an important role in hyperglycemia-aggravated BBB disruption in stroke and provide a novel therapeutic target for hyperglycemic stroke.

Title: NRF-2 activation protects ischemic white matter injury

Authors: *S. K. AGRAWAL[1], V. KESHERWANI[2], F. ATIF[3], S. YUSUF[3];

[3]Emory Univ., Atlanta, GA

Abstract: Background: Oxidative stress damage plays a vital role in spinal ischemic injury. The nuclear factor erythroid 2-related factor (Nrf2) signaling pathway can be activated by cellular oxidative stress. Resveratrol, a plant-derived polyphenolic compound, has antioxidant property. Recent studies have demonstrated that resveratrol has protective effects against ischemic injury, however, its mechanism of action is not known. In the present study, we have studied neuroprotective effect of resveratrol and role of Nrf-2 in spinal cord ischemic injury.
Methods: Spinal cord was removed from adult male Wistar rats from T2-T10 and was used to induce ischemic injury in vitro with and without treatment with resveratrol (50μM). Electrophysiological recording of compound action potential (CAP) and oxidative stress was evaluated by biochemical assays. Pathological changes of spinal cord tissue were observed by Hemotxilin and Eosin (H & E) Staining and Western blot was used to quantify protein

expression levels of Glial Fribrillary Acidic Protein (GFAP) and Nrf2.
Results: We found significant changes in spinal cord white matter compound action potential (CAP) and H&E staining showed that resveratrol significantly improved neuronal injury. The biochemical assays showed significant changes in lipid peroxidase (LPO), glutathione peroxidase (GSH), superoxide dismutase (SOD), protein carbonyl (PC), mitochondrial energy (ATP) and mitochondrial Ca++. Further, we found significant increase in nuclear NrF-2 expression in nucleus with immunohistochemistry and western blotting and down regulation of GFAP content after resveratrol treatment as compared to injury.
Conclusion: The present results showed that resveratrol pretreatment had neuroprotective effects on compound action potential, Ca++ loading and biochemical parameters after ischemic injury. The neuroprotective effect is likely to be exerted by upregulated expression of transcription factor Nrf-2 to ameliorate the oxidative damage and preserving mitochondrial function.

Title: Cortical mapping of circuits affected by intracerebral hemorrhage in the mouse

Authors: *T. LANMAN, H. C. BARRATT, S. T. CARMICHAEL;
Neurol., David Geffen Sch. of Med., Los Angeles, CA

Abstract: Stroke is the fourth leading cause of death and the leading cause of adult disability in the United States. Intracerebral hemorrhage (ICH) represents a stroke type characterized by a high rate of mortality and disability. The processes of tissue repair and recovery following ICH have not been identified. ICH produces a sizeable region of cell death in the hemorrhage cavity. This study uses a retrograde neuronal tracer, Cholera Toxin Subunit B (CTb), to selectively label neurons projecting to the hemorrhage zone, which in the left striatum. The goal is to identify the cortical circuits that are affected, or disconnected, by the striatal damage from experimental ICH. Two models have been developed to simulate human ICH stroke in mice: Autologous Tail Blood Infusion (ATBI) and Collagenase Infusion (CI). Each models different aspects of ICH in humans. CTb was co-infused in conjunction with blood or collagenase with each model and with a saline control. This facilitates the comparison of the cortical distribution of neuronal

projections to the region of damaged striatum between hemorrhage and baseline in addition to comparing the distribution between the two ICH models. Labeled neurons were mapped with a computer-interfaced microscopic mapping program. Differences between stroke/baseline and between ATBI/CI were observed, thus indicating which areas of the cortex gained and lost neuronal links, or communication, with the damaged tissue following stroke. Preliminary study indicates differences in the ratio of contralesional projections to ipsilesional projections between stroke/baseline and ATBI/CI. The implications of these results will provide insight into the post-hemorrhagic stroke environment so that specific and effective treatments and therapies may be developed.

Title: Tumor necrosis factor related apoptosis inducing ligand determines loss of the neuroprotective effect of preconditioning in rats undergone transient middle cerebral artery occlusion

Authors: *G. CANTARELLA[1], G. DI BENEDETTO[1], G. PIGNATARO[2], L. ANNUNZIATO[2], R. BERNARDINI[1];
[1]Clin. and Mol. Biomedicine, Section of Pharmacol. and Biochem., Univ. of Catania, Med. School, Italy, Catania, Italy; [2]Dept. of Neurosciences, Div. of Pharmacology, Med. Sch., Federico II Univ. of Naples, Naples, Italy

Abstract: The brain's resistance to ischemic injury can be transiently augmented by neuronal ischemic preconditioning (IPC), an endogenous neuroprotective modality by which a sub-lethal insult confers temporary protection against subsequent lethal ischemia. The preconditioning stimulus is recognized by molecular sensors, such as neurotransmitters, neuromodulators, cytokines and toll-like receptors, as well as ion channels and redox-sensitive enzymes. Cytokines are known to have an important role in acute stroke. A candidate protein involved in ischemic neuronal death is the Tumor Necrosis Factor Related Apoptosis Inducing Ligand (TRAIL). We thus studied the role of TRAIL and its receptors in the pathophysiology of stroke and ischemic preconditioning (IPC) in rats subjected to transient middle cerebral artery occlusion (tMCAO). Data showed that TRAIL and its death receptors are up-regulated in cerebral ischemia, while

their down-regulation occurs when IPC is applied. Consistently, i.c.v. injection of TRAIL abrogates beneficial effects of IPC. Finally, to corroborate the hypothesis of a detrimental role of TRAIL in the ischemic rat brain, a TRAIL neutralizing antibody (CD253) was injected i.c.v. in rats subjected to tMCAO. The anti-TRAIL antibody exerted significant neuroprotective effects in rats subjected to tMCAO, with parallel amelioration of neurological deficits. All together, these data show that TRAIL is a deleterious factor in the pathogenesis of ischemia-related neuronal damage, and that the prevention of TRAIL effects in the brain may represent a novel neuroprotective strategy for treatment of stroke.

Med., Tainan, Taiwan; [3]Inst. of Life Science, Natl. Def. Med. Ctr., Taipei, Taiwan; [4]Inst. of Mol. Biology, Academia Sinica., Taipei, Taiwan

Abstract: The major brain diseases involve Alzheimer`s disease (AD), frontal temporal lobar degeneration (FTLD), and stroke…etc. More recent studies has focused on dementia with Aβ aggregations and TDP-43 inclusions, dementia after stroke and vascular contributions to cognitive decline and depression in later life, however, the efficient therapeutic strategies to cure these troublesome diseases are still in shortage. To date, several studies have provided evidence with regard to the neuroprotection benefits of hyperbaric oxygen (HBO) therapy in cases of trauma and brain disease, besides the improvements of bone marrow stem cells (BMSCs) proliferation and mobilization may also are involved in the therapeutic effects of HBO. Even

thought HBO has been used as a primary or adjunctive therapy over years, the course of therapeutic window is still controversial, whether long course HBO therapy improves a better prognosis is still an open question in brain diseases, in addition, the therapeutic mechanism of HBO-induced neuroprotection and functional recovery is still unexplored. We have generated the FTLD-U mouse model (CaMKII-TDP-43 transgenic mice) by overexpression of TDP-43 in the forebrain and the phenotypic characteristics mimicking those of FTLD. The middle cerebral artery occlusion (MCAO) rat stroke model is also applied on our researches. Hence, this study investigates the effects of HBO therapy on the migration of BMSCs, neurogenesis, gliosis, inflammation response and behavior performance. Our preliminary data indicated there was a better recovery of behavior performance in the three-week HBO group when compared with the two-day HBO group. Mobilization of BMSCs to the brain damaged area was more improved in long course HBO treatments, suggesting the duration of therapy is crucial for promoting the homing of BMSCs to injury brain by HBO therapies. HBO also can stimulate expression of trophic factors and improve neurogenesis and gliosis. These effects may help in neuronal repair after brain damage or degeneration, and increasing the course of HBO therapy might enhance therapeutic effects.

Title: Time-dependent formation/elimination of nucleic γ-H2AX and its cytosolic distribution in a rat hippocampal neuron culture model of ischemic stroke

Authors: *A. I. MARTIN[1], R. D. SWEAZEY[1], B. C. HONG-GOKA[2,1], F.-L. F. CHANG[1]; [1]Indiana Univ. Sch. of Med. - Fort Wayne, Fort Wayne, IN; [2]UCSF - Fresno Alzheimer's & Memory Ctr., Fresno, CA

Abstract: Stroke is a major health issue often resulting in death or disability. Many factors contribute to the cellular damage resulting from the complex and multistage processes of hypoxic ischemia. The precise biochemical events that account for the death of hippocampal neurons either by apoptosis or necrosis during hypoxia remain poorly understood. While delayed cell death in the brain under ischemic conditions has been documented in humans and

experimental models, the early molecular events occurring before reperfusion and determining the extent of cellular loss are less well understood. Thus, we investigated the time course of γ-H2AX formation and elimination in an oxygen and glucose deprivation (OGD) model of ischemia in primary rat postnatal hippocampal neuron-rich culture. γ-H2AX is the phosphorylated variant of the H2A protein family, which is a component of the histone octomer in nucleosomes and is phosphorylated by kinases as the first step in recruiting and localizing DNA repair proteins. It has been used effectively as a marker for DNA damage detecting DNA double-strand breaks (DSBs) in tissues from patients with chronic obstructive pulmonary disease, solid tumors, or myeloid leukemia.
Using fluorescent immunocytochemical techniques, our results show that H2AX becomes increasingly phosphorylated with increasing OGD duration, peaking between 2 and 4 hours of OGD and reversing to normoxic levels at 8 hours OGD. In agreement with published reports, bright nuclear foci and diffuse nuclear staining were seen in a time-dependent fashion in apoptotic cells depicting the nuclear accumulation of γ-H2AX at the DNA damage sites. Extended durations of OGD produced γ-H2AX negative cells that were characterized as late-apoptotic or undergoing DNA repair. In addition, we also observed a more diffuse staining in the cytoplasm and axon hillock of some cells exposed to OGD, suggesting a possible pre-apoptotic modification of H2AX. Investigations of these different γ-H2AX staining patterns (nucleic vs. cytosolic) and underlying mechanisms are ongoing. We believe that γ-H2AX, a well-documented early, sensitive, and selective marker of DNA double-strand breaks, is useful in the identification and quantification of ischemic neurons that are compromised, yet salvageable and that it provides a unique opportunity to test potential new treatments for hypoxic ischemia.

Title: Quantifying hemodynamic changes in a transient filament model of focal cerebral ischemia with 2d optical imaging spectroscopy

Authors: *F. BURROWS[1], A. DENES[2], N. BRAY[2], S. ALLAN[2], I. SCHIESSL[2];
[1]Univ. Of Manchester, Manchester, United Kingdom; [2]Univ. of Manchester, Manchester, United Kingdom

Abstract: The aim of this study is to develop a novel model of transient cerebral ischaemia for functional brain imaging with high spatial and temporal resolution. Furthermore we developed spectroscopic mulitwavelength analysis to quantify the dynamic changes in cortical blood perfusion before, during and after induced cerebral ischaemia in anesthetized mice.
Middle cerebral artery occlusion (MCAo) was induced by advancing a novel remote filament along the internal carotid artery to occlude the middle cerebral artery. Using the remote filament it is possible to gain baseline recordings of the cerebral vasculature before induced stroke and subsequent recordings during and after for upto 6 hours of reperfusion.
2D optical imaging spectroscopy with four different wavelengths of illumination allows the calculation of micromolar changes in the concentration of heamodynamic parameters; oxy-, deoxy- and total haemoglobin.
Our results show the expected decrease in the concentration of oxyhaemoglobin in the occluded MCA and supplying cortical regions compared to baseline. After removal of the filament, the MCA shows an increase in oxyhaemoglobin concentration even though large areas of the cortex which are supplied by this vessel are insufficiently reperfused even several hours after the stroke. These findings support the idea of a 'no-reflow' phenomenum.
Our results suggest that 2D optical imaging spectroscopy with the novel remote filament approach enables precise mapping of vascular and metabolic changes in the mouse MCAo model. Obtaining baseline recordings makes this a powerful model with multiple applications contributing to better understanding of ischaemic-induced changes in the brain

Title: Role of AMPA receptors in homocysteine-NMDA receptor mediated crosstalk between ERK and p38 MAP kinase

Authors: *R. PODDAR, S. PAUL;
Neurol., Univ. of New Mexico, ALBUQUERQUE, NM

Abstract: Hyperhomocysteinemia or systemic elevation of homocysteine is considered to be a major risk factor for neurodegenerative disorders but little is known about the underlying mechanisms involved in homocysteine mediated neuronal cell death. Since homocysteine is a known agonist of N-methyl-D-aspartate receptors (NMDAR), it had been assumed that homocysteine activates NMDA-mediated intracellular pathways in ways analogous to the prototype NMDAR agonist, glutamate. However, recently we have shown that the effects of homocysteine and glutamate on NMDAR activation and subsequent downstream signaling are quite different. While glutamate-mediated neuronal death involves activation of NR2B subunit containing NMDAR (NR2B-NMDAR), our findings showed that homocysteine-induced neuronal death involves stimulation of NR2A subunit containing NMDAR (NR2A-NMDAR) that are generally thought to be involved in neuronal survival. Our findings also showed that glutamate-NMDAR stimulation leads to a transient activation of ERK MAPK (extracellular-signal regulated mitogen activated protein kinase) that plays a role in neuronal survival. In contrast, homocysteine-NR2A NMDAR mediated activation of ERK MAPK is sustained, which leads to neuronal cell death. More recently, we showed that stress-induced p38 MAPK also plays a role in homocysteine-NMDAR induced neuronal death. We further established that homocysteine-mediated neurotoxicity involves a novel interplay between ERK and p38 MAPK, where activation of p38 MAPK is downstream of, and dependent on ERK MAPK.
The goal of the present study is to evaluate the underlying signaling mechanism(s) involved in homocysteine-mediated crosstalk between ERK and p38 MAPK. Using cortical neuronal cultures we show that inhibition of amino-3-hydroxy-5-methyl-4-isoxazolepropionate receptors (AMPAR) with CNQX blocks homocysteine-mediated phosphorylation of p38 MAPK but had no effect on ERK MAPK phosphorylation suggesting that AMPAR plays an intermediary role in facilitating the crosstalk between ERK and p38 MAPK. Using surface biotinylation studies we further show that treatment with homocysteine leads to internalization of GluR2-AMPAR subunits from cell surface. ERK MAPK inhibitor PD98059 attenuates this effect of homocysteine on GluR2-AMPAR. Consistent with these findings inhibition of GluR2-lacking AMPARs with NASPM significantly reduces p38 MAPK phosphorylation and subsequent cell death. These findings suggest that homocysteine-ERK MAPK dependent decrease in surface GluR2-AMPAR increases Ca2+ influx through GluR2-lacking AMPAR resulting in activation of p38 MAPK and subsequent neuronal cell death.

Title: Intracerebroventricular administration of interleukin-1β elevates brain kynurenic acid and disrupts PPI in C57BL/6 mice

Authors: S. CALDWELL[1], M. LARSSON[2], M. KAMENSKI[1], L. SCHWIELER[2], G. ENGBERG[2], V. B. RISBROUGH[1,3], S. ERHARDT[2], *S. B. POWELL[1,3];
[1]UCSD, LA JOLLA, CA; [2]Physiol. and Pharmacol., Karolinska Institutet, Stockholm, Sweden; [3]VA Ctr. of Excellence for Stress and Mental Hlth., La Jolla, CA

Abstract: *Background*: Interleukin-1 beta (IL-1β) is a cytokine protein (member of the interleukin 1 cytokine family) and an important mediator of the inflammatory response. Patients with schizophrenia and bipolar disorder, particularly those that have had a psychotic episode, present elevated levels of IL-1β and kynurenic acid (KYNA). KYNA is produced via the kynurenine pathway of tryptophan metabolism, and immune activation can shift tryptophan metabolism from 5-HT to l-kynurenine. In rodents, pharmacologically elevated levels of KYNA have been shown to disrupt prepulse inhibition of startle (PPI). The aim of the present study was to investigate whether IL-1β influences the synthesis of brain KYNA in mice and if administration of IL-1β affects PPI. *Methods*: IL-1β was injected intracerebroventricularly (ICV) at doses 0.5, 5 and 50 ng. Mice were tested in startle and PPI every hour for 6 hours. Weight and temperature of the mice were also recorded every hour. Another set of C57BL/6 mice were injected ICV with 0.5, 1, 5, or 10 ng of IL-1β and the animals were euthanized and brain KYNA was quantified by means of HPLC 6 hours post-injection. *Results*: ICV administration of IL-1β disrupted PPI at the lowest dose tested (0.5 ng; $p<0.05$). Higher dose of IL-1β decreased startle magnitude. Administration of 0.5 ng IL-1β, but not 1, 5, or 10 ng, significantly elevated brain KYNA levels compared to vehicle (9.49 ± 1.88 nM *vs.* 3.40 ± 0.51 nM , $p < 0.05$). *Discussion*: Notably, only administration of the lowest dose of IL-1β disrupted PPI, indicating that this effect may be mediated by the increased brain KYNA concentrations observed at this dose. These data support the hypothesis that IL-1β and KYNA are important players in the pathophysiology of psychotic diseases such as schizophrenia and bipolar disorder.

Title: Surgery affects synaptic plasticity and astrocyte activity contributing to postoperative cognitive decline

Authors: M. GÓMEZ[1], T. YANG[1], M. LINDSKOG[2], L. ERIKSSON[1], *N. TERRANDO[1]; [2]Neurosci., [1]Karolinska Institutet, Stockholm, Sweden

Abstract: Background: Recovery from major surgery or critical illness is often accompanied by disturbances in cognitive domains and is a major clinical problem of unclear etiology. Activation of the innate immunity, pro-inflammatory cytokine release and neuroinflammation are putative mechanisms underlying cognitive dysfunction in preclinical surgical models, yet the mechanisms whereby systemic injury affects CNS function remain unclear. Herein we explore the effects of surgery on synaptic plasticity and neuroinflammation following orthopedic surgery under general anesthesia.
Methods: We used 11-14-wk-old male wildtype (WT) C57BL/6 and randomly assigned to untreated control animals with analgesia or surgery (an open tibial fracture of the left hind leg with intramedullary fixation) under isoflurane general anesthesia and postoperative analgesia. Separate cohorts of animals were used to assess synaptic plasticity, systemic and central inflammatory changes including astrocytes (GFAP) immunofluorescence, and hippocampal-dependent cognition using trace fear conditioning (TFC).
Results: Aside a key role of myeloid-derived peripheral macrophages in penetrating the blood-brain barrier after surgery, we now found distinct changes in astrocytes activation and morphology. Reactive astrocytes, with enlarged cell bodies and reduced filaments, were observed 24h after surgery. Astrocytic alteration was further associated with impaired pre-synaptic facilitation and long-term potentiation (LTP) deficit starting at 24h and further decreasing 72h postoperatively (figure 1). At 72h, surgical animals were also tested with TFC to assess hippocampal-dependent memory function and further displayed memory dysfunction ($P<0.001$).

Conclusion: Peripheral surgery affects synaptic transmission and plasticity causing postoperative cognitive decline. Neuroinflammation, including astrocyte activation, may be pathological hallmarks in surgery-induced cognitive decline.

Title: Misoprostol protects brain against intracerebral hemorrhage

Authors: *J. WANG, H. WU, T. WU, X. ZHAO, W. CHEN;
Anesthesiology/Critical Care Med., Johns Hopkins Univ., Sch. of Med., BALTIMORE, MD

Abstract: Intracerebral hemorrhage (ICH) is a devastating form of stroke that leads to significant disability in survivors. Misoprostol, a synthetic PGE_1 analog and PGE_2 receptor agonist, has shown protection against cerebral ischemia. In this study, we tested the efficacy of misoprostol in 12-month-old mice subjected to collagenase-induced ICH. We also investigated its potential mechanism of action. In the present study, ICH was induced by intrastriatal injection

of collagenase, and mice were randomly assigned to receive subcutaneous injections of misoprostol or vehicle. Neurologic deficits were examined on days 3 and 28 after ICH. Some mice were sacrificed after 1 day for measurement of superoxide production, protein oxidation, gelatinolytic activity, HMGB1 expression, Src kinase activity, and cytokine interleukin-1β expression. Others were sacrificed on day 3 for measurement of brain injury volume, swelling, edema, neuronal death, and cellular inflammatory response. Misoprostol post-treatment decreased brain swelling and lesion volume and improved long-term neurologic function. However, misoprostol significantly increased the incidence of diarrhea without significantly increasing body weight loss or mortality. Misoprostol post-treatment decreased cellular inflammatory response, including microglia/macrophage and astrocyte activation and neutrophil infiltration; attenuated oxidative brain damage and gelatinolytic activity; and decreased HMGB1 expression, Src kinase activity, and interleukin-1β expression without affecting cyclooxygenase-2 expression. These results indicate that misoprostol protects brain against ICH injury through mechanisms that may involve the HMGB1, Src kinase, and MMP-2/9 pathway; however, the high incidence of diarrhea could be a concern for its clinical use.

Title: Plasma levels of neuron specific enolase quantifies the extent of neuronal injury in murine models of ischemic stroke and multiple sclerosis

Authors: *T. DAEHN[1], M. GELDERBLOM[1], B. SCHATTLING[2], P. LUDEWIG[1], C. BERNREUTHER[1], P. ARUNACHALAM[1], M. GLATZEL[1], C. GERLOFF[1], M. A. FRIESE[2], T. MAGNUS[1];
[1]Univ. Hosp. Hamburg-Eppendorf, Hamburg, Germany; [2]Zentrum für molekulare Neurobiologie Hamburg (ZMNH), Hamburg, Germany

Abstract: Objective: We aimed at validating a plasma biomarker for neuronal damage that can be used in acute and chronic models of neurological diseases.
Methods: We investigated two different models, middle cerebral artery occlusion followed by reperfusion and MOG35-55-induced experimental autoimmune encephalomyelitis (EAE). In stroke experiments we measured infarct sizes by magnetic resonance imaging and vital stainings

and correlated them with plasma levels of neuron specific enolase (NSE) at different time points after reperfusion. Equally, in EAE experiments, we correlated NSE levels with neurological scores and histopathological damage of axons at different time points. We detected plasma NSE levels by ELISA.
Results: Plasma NSE levels correlated significantly with stroke size and EAE score. Investigations into the dynamics of neuronal loss over time correlated well with the dynamics of NSE levels. NSE even predicted the onset of EAE, before clinical signs were recordable.
Conclusions: Plasma NSE is a valid and simple experimental biomarker that allows quantifying the degree of neuronal injury in a non-invasive approach.

Title: Selective P2X7 receptor antagonists inhibit Bz-ATP induced IL-1β release in the rat brain

Authors: *I. FRASER, L. ALUISIO, P. BONAVENTURE, B. SAVALL, M. LETAVIC, N. CARRUTHERS, T. LOVENBERG, A. BHATTACHARYA;
Janssen, SAN DIEGO, CA

Abstract: The P2X7 receptor plays an important role in the release of pro-inflammatory cytokines (IL-1β, IL-18) from cells of the immune system in both the periphery and the central nervous system. It has been demonstrated that extracellular release of mature IL-1β is dependent on ATP-sensitive P2X7 activation. IL-1β released from glial cells may play a role in initiating the neuroinflammatory cascade in the brain, possibly leading to various neuropsychiatric and neurodegenerative disorders. Therefore, the P2X7 receptor has become an attractive drug target for the treatment of diseases that involve neuroimmune processes. Here we report on a new dialysis method to detect IL-1β directly from the hippocampus of freely moving rodents. To validate this new method, we tested the effect of the P2X7 agonist dibenzoyl-ATP (Bz-ATP) in wild type (WT) and P2X7 knockout (KO) mice. Additionally, three brain penetrant P2X7 antagonists, Compound A (2-Methyl-N-{[1-(4-phenylpiperazin-1-yl)cyclohexyl]methyl}-1,2,3,4-tetrahydroisoquinoline-5-carboxamide), Compound B (N-{[4-(4-Phenylpiperazin-1-

yl)tetrahydro-2H-pyran-4-yl]methyl}-2-(phenylsulfanyl)pyridine-3-carboxamide) and Compound C were tested on Bz-ATP-induced IL-1β release in the rat hippocampus. Bz-ATP was found to increase IL-1β release in the hippocampus of WT but not P2X7 KO mice. The three structurally distinct P2X7R antagonists inhibited Bz-ATP induced IL-1β release in the rat hippocampus. Taken together these data show evidence that treatment with a P2X7 receptor antagonist may modulate pro-inflammatory cytokines involved in neuroinflammatory diseases.

Title: Single high dose methamphetamine recruits dopamine transporter and parkin to rat striatal terminals in a microtubule dependent manner

Authors: *B. A. KILLINGER, A. MOSZCZYNSKA;
Dept. of Pharmaceut. Sciences, EACPHS, Wayne State Univ., Detroit, MI

Abstract:
Methamphetamine (METH) is a potent psychostimulant that can cause toxicity to both dopaminergic (DAergic) and serotonergic (5HTergic) nerve terminals in the striatum. METH inhibits and reverses the function of dopamine transporter (DAT); the membrane bound protein responsible for the reuptake of dopamine (DA) from the synapse. The regulation of DA influx/efflux across the presynaptic terminal of DAergic terminals via DAT is the primary factor mediating METH neurotoxicity. The efficient trafficking of membrane-bound proteins to their cellular targets is required for the protein to retain proper functioning. However, the regulation of DAT protein trafficking in response to METH is still poorly understood. In vitro, METH causes a transient recruitment of DAT to the presynaptic membrane, but in vivo METH administration does not effect localization of DAT in the presynaptic nerve terminals. In cultured cells, the

interaction of E3 ligase parkin with DAT inhibits the activity of DAT at the presynaptic membrane and the disruption of microtubule polymerization increases membrane expression of DAT. Previously, our lab have found that acute administration of METH quickly increases total levels of both parkin and DAT in the rat striatum suggesting that METH quickly increases DAT trafficking in a parkin dependent manner. The current study investigated whether this METH induced recruitment of DAT via parkin was dependent upon microtubule polymerization. We found that intracerebroventricular injection of the microtubule polymerization inhibitor, colchicine, increased the membrane expression of DAT. Furthermore pre-treatment with colchicine prior to IV METH inhibited the increase in DAT levels in the striatum. Our results suggest that, in vivo, the METH induced trafficking of DAT to the striatal presynaptic membrane depends upon both its interaction with parkin and the polymerized microtubules. This further supports the in vivo role of DAT trafficking in the early cellular response to METH.

Title: Lipocalin-2 induction in sterile neuroinflammation: A marker for neuronal cell death

Authors: M. BANJARA[1], K. BENNETT[3], A. FERNANDEZ[2], *J. STOLL[4];
[1]Biomed. Sci., Texas Tech. Sch. of Pharm., AMARILLO, TX; [2]Biomed. Sci., Texas Tech. Sch. of Pharm., Amarillo, TX; [3]Lab. Sci. and Primary Care, Texas Tech. Univ. HSC, Lubbock, TX; [4]Biomed. Sci., Texas Tech. Sch. Pharm., AMARILLO, TX

Abstract: Lipocalin-2 (LCN2) is a bacteriostatic protein that sequesters siderophore-bound iron and is induced by lipopolysaccharide in C6 astroglial cells and cultured astrocytes. LCN2 is also induced in aseptic neuroinflammation. However, the role in sterile neuroinflammation is unknown and we undertook studies to understand its function. An in vitro model was developed where cells were treated necrotic cell extract and LCN2 induction was measured by quantitative RT-PCR and western blot. We also measured the induction of LCN2 in vivo in two mouse epilepsy models: pilocarpine-induced status epilepticus (SE) or corneal kindling. LCN2 was induced in hippocampus of SE mice, but not in corneal kindled mice. Induction in SE mice was maximal at 3 days post-SE, corresponding to the day of maximum cell death. Induced LCN2

declined to basal levels by 21 days post-SE along with cell death. Kindled mice did not show hippocampal cell death at any time. These data suggest LCN2 may be a marker of pathological cell death. It is believed that damage-associated molecular patterns, released by necrotic cells, alert the innate immune system during inflammatory insults. Thus, we decided to identify the molecule(s) from dead cells that trigger LCN2 expression. C6 cells treated with 300µg/ml necrotic Neuro2A cell extract for 18-24 hrs induced LCN2 mRNA from 5- to 550-fold in several different preparations. Necrotic cell extract did not induce LCN2 expression in cultured astrocytes. However, basal LCN2 was high in primary astrocytes perhaps due to exposure to dead cells during culture preparation. In fact, the supernate following centrifugation of isolated astrocytes induced LCN2 expression in C6 cells. LCN2 induction in C6 cells was blocked by NF-κB nuclear translocation inhibitor, Bay11-7082. The LCN2 promoter contains a NF-κB response element and this may explain the induction of LCN2 mRNA. Induction was inhibited 47% by FPS-ZM1, a RAGE receptor antagonist but not by IL-1RA. VIPER, a peptide that inhibits TLR4 signal transduction inhibited LCN2 mRNA induction by 27%. These data suggest multiple proteins in the extract are responsible for induction. However, a cytokine array failed to show elevated cytokines, ruling out their role. The necrotic extract was fractionated by gel filtration chromatography as a step to identify the responsible molecules. However, every fraction eluting from the column showed inducing activity, thus confirming that multiple proteins are involved. We propose, based on the diversity of the inducer proteins, that the induction is due to non-specific structural alterations of necrotic proteins rather than the release of specific inducer proteins.

Title: Emotional and cognitive behaviour changes are associated with increased corticosterone and changes in glutamatergic transmission in the early stages of experimental allergic encephalomyelitis (EAE), a mouse model of multiple sclerosis

Authors: *S. ACHARJEE[1], N. NAYANI[1], M. TSUTSUI[1], M. N. HILL[2], S. S. OUSMAN[3], Q. J. PITTMAN[1];

[1]Dept. of Physiol. and Pharmacology, Hotchkiss Brain Inst., [2]Dept. of Cell Biol. and Anatomy, Hotchkiss Brain Inst., [3]Dept. of Clin. Neurosciences, Hotchkiss Brain Inst., Univ. of Calgary, Calgary, AB, Canada

Abstract: Multiple sclerosis (MS) is often associated with co-morbid neuropsychiatric and cognitive impairments, affecting around 50% of MS patients. Herein, we investigated these abnormalities in an animal model of MS, called EAE, during the presymptomatic stage of the disease.
EAE was induced by immunization with MOG35-55 and the mice exhibited no motor deficits until d9 after immunization. This enabled us to carry out a series of neurobehavioral tests between d6-d8 post-immunization. EAE mice spent more time in the outer zone in open field test and in the closed arms of elevated plus maze, and showed decreased latency for immobility in tail suspension test and forced swim test compared with controls, which were indicative of anxiety- and depression- like behavior. EAE mice spent less time in the target quadrant compared to sham controls during probe trial in Morris water maze while in fear conditioning test, it displayed a trend towards faster memory extinction, indicative of memory impairment. No demyelination, microglial activation or astrogliosis was observed in the brain at this stage. Transcript analysis by RT-PCR from the brain revealed elevated IL-1β and TNF-α in the hypothalamus of EAE mice. This was associated with increased plasma corticosterone levels in EAE mice compared to control. To investigate the neuronal correlate of these behaviour changes, whole-cell recording was carried out in the principal neurons of the basolateral amygdala. There was no difference in the membrane excitability (action potential threshold and firing rate) between control and EAE mice. Investigation into glutamatergic synaptic transmission revealed increased frequency of the mini-excitatory postsynaptic currents (mEPSC) without any changes in amplitude compared to the controls; however, the paired pulse ratio of the evoked EPSCs was increased implying decreased release probability.
In conclusion, emotional and cognitive deficits are observed in EAE (and possibly MS) in the absence of demyelination and was associated with inflammatory and HPA axis changes and changes in glutamatergic synapses.

Title: Determining the mechanism of orexin A induced neuroprotection in an *Ex vivi* arcuate nucleus model

Authors: *C. M. DUFFY[1], C. J. BILLINGTON[5,2], C. M. KOTZ[5,3,4], J. P. NIXON[5,4], T. A. BUTTERICK[5,4];
[1]Food Sci. and Nutr., Univ. of Minnesota, St Paul, MN; [2]Dept. of Med., [3]Dept. of Neurosci., Univ. of Minnesota, Minneapolis, MN; [4]Food Sci. & Nutr., Univ. of Minnesota, St. Paul, MN; [5]VA Med. Ctr., Minneapolis, MN

Abstract: Diets rich in saturated fatty acids such as palmitic acid increase oxidative stress, apoptosis, and pro-inflammatory cytokines in both peripheral tissue and the central nervous system, including the cerebral cortex and the hypothalamus. High fat diets have also been shown to induce neuronal degeneration of sites important to regulating energy balance, such the arcuate nucleus, but the underlying cause of this dysregulation remains unclear. In cell culture models, palmitic acid increases lipid peroxidation and increases cell death, and in an in vitro adult mouse hypothalamic cell culture model, we showed that orexin A (hypocretin) reduces lipid peroxidation, decreases caspase 3/7 activity induced by palmitic acid and stabilizes B-cell lymphoma-2 (Bcl-2). These data suggest that orexin A may be neuroprotective, but the mechanism underlying this effect is unknown. We hypothesized that a potential mechanism could be gene expression stabilization of the anti-apoptotic protein Bcl-2. To test this possibility, we used an organotypic “ex vivo” brain model, using a micropunch of the arcuate nucleus which allowed for pharmacological manipulation while preserving the functional integrity of the arcuate nucleus network. Arcuate nucleus tissue explants were isolated from Sprague-Dawley rat brains, and exposed to either palmitic acid (0.075 mM) or control solution. Following 24 hour of palmitic acid exposure (or not), cell viability was tested using a resazurin-based assay. In the palmitic acid treated explants, there was a significant decrease in cell viability ($p < 0.05$) compared to controls, suggesting the stabilization of Bcl-2. We are currently evaluating mechanisms of orexin A-induced neuroprotection in arcuate nucleus explants following chronic palmitic acid treatment in the presence or absence of OxA, and measuring changes in pro- and anti-apoptotic gene expression such as Bcl-2 family members. Based on cell culture models, we hypothesize that OxA will increase viability of Arc explants during PA challenge. Collectively, this data will be used to gain further insight into mechanisms of OxA-induced neuroprotection.

Title: Complex response of brain endothelial cells to hypoxia: Implications for Alzheimer's disease

Authors: J. LUO, A. PANDEY, X. YIN, *J. M. MARTINEZ, P. GRAMMAS;
Garrison Inst. On Aging At Texas Tech. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Hypoxia is increasingly recognized as an important contributing factor to the development of brain diseases such as Alzheimer's disease (AD). Although hypoxia is a powerful regulator of angiogenesis in the periphery the response of brain endothelial cells to hypoxic challenge appears to be unique. We have previously demonstrated that exposure of brain endothelial cell cultures to hypoxia resulted in a significant decrease in tube length, an in vitro index of angiogenesis, despite increases in several pro-angiogenic proteins. The objective of this study was to further explore the biochemical processes that regulate the response of brain endothelial cells to hypoxia. Brain endothelial cell cultures were initiated from isolated rat brain microvessels and subjected to hypoxia (1% O2) for various time periods. The results showed that hypoxia induced rapid ($\leq$ 0.5h) expression of hypoxia-inducible factor 1α (HIF-1α) and that cell viability, assessed by MTT assay, was unaffected within the first 8 h. While hypoxic exposure of brain endothelial cell cultures evoked a decrease in tube length (angiogenesis) it did not induce apoptosis. On the contrary, apoptosis induced by nutrient deprivation in these cultures was mitigated by hypoxia. Treatment of endothelial cell cultures with resveratrol evoked an increase in apoptotic signaling as indicated by expression of apoptosis-related proteins, cleaved caspase 3, Bim 1 and phospho-p53. The blunted angiogenic response detected in hypoxic cultures was partially reversed with reveratrol pretreatment, implicating apoptotic signaling in angiogenesis. The idea that there are overlapping or common mechanisms in apoptosis and angiogenesis in brain endothelial cells is supported by data which showed that brain endothelial cells grown under normoxic conditions and exposed to the apoptosis inhibitor pifithrin (30 μM) demonstrated impaired angiogenesis. Taken together these data implicate a complex relationship in the cerebral microcirculation among hypoxia, apoptosis and angiogenesis and suggest that targeting mechanisms and/or mediators that drive endothelial activation toward angiogenesis may be useful in AD and other diseases characterized by cerebral hypoxia.

Title: Chronic low-dose methylmercury treatment disrupts mitochondrial ATP production of striatal synaptosomes in male BALB/c mice

Authors: *S. M. FOX, W. D. ATCHISON;
Dept. of Pharmacol. and Toxicology, Michigan State Univ., East Lansing, MI

Abstract: Methylmercury (MeHg) is an environmental contaminant that causes cell-type specific damage to the central nervous system in a calcium (Ca^{2+}) dependent manner. *In vitro* acute application of MeHg results in a time- and concentration-dependent biphasic increase in intracellular Ca^{2+} ($[Ca^{2+}]_i$). Treatment with voltage-gated calcium channel (VGCC) antagonists delay the MeHg-induced Ca^{2+}-increase. MeHg targets mitochondrial regulation by causing decreased Ca^{2+} uptake, increased Ca^{2+} release, opening of the mitochondrial permeability transition pore, and disruption of oxidative phosphorylation. The acute effects of MeHg have been investigated extensively however the effects of chronic low-dose exposure have not been characterized. The objective of this study was to investigate the effects of an *in vivo* chronic low-dose MeHg treatment on mitochondrial function of nigrostriatal dopamine (NSDA) neuron synaptosomes and whether co-treatment with the VGCC antagonist, isradipine, would prevent MeHg-induced changes. The NSDA cell bodies are located in the midbrain and they project their axons to the striatum. These neurons exhibit a unique physiological phenotype; they autonomously generate action potentials in the absence of synaptic input. The spontaneous action potentials rely on the influx of Ca^{2+} through Cav1.3, L-type Ca^{2+} channels. Male Balb/c mice were given free access to 0 or 6.25 ppm Hg as MeHg in their drinking water and 0 or 2 ppm isradipine in their feed. Following a 12mo treatment striatal synaptosome mitochondrial basal respiration, ATP production, maximal respiration, and spare capacity were measured using an Extracellular Flux Analyzer. MeHg treatment alone tended to decrease ATP production. Co-treatment with the VGCC antagonist isradipine resulted in a significant increase in ATP production compared to isradipine or MeHg treatment alone. Treatment had no effect on basal

respiration, maximum respiration, or spare capacity. These data suggest chronic low-dose MeHg treatment induces mitochondrial dysfunction resulting in decreased ATP production in striatal synaptosomes. Isradipine co-treatment was able to prevent the MeHg-induced decrease in ATP production suggesting that MeHg-induced damage is dependent on functional VGCC's in this chronic treatment paradigm. This work was supported by a ViCTOR supplement to R01ES03299.

Abstract: Ozone (O_3), a component of air pollution has a significant impact on public health. The O_3 is a highly reactive gas that oxidizes molecules in the biological systems and reacts with cell membranes inducing the formation of reactive oxygen species that produce the accumulation of oxide derivates and inflammatory processes in airway epithelial cells. Central nervous system (CNS) also has been affected, experimentally induce changes in sleep patterns and neurotransmitters related to sleep following O_3 exposure these changes were revert by anti-inflammatory drug administration. In the present study we analyze the airway inflammatory response produced by O_3 exposure and its consequences in the CNS in both acute and chronic exposure. We use the ELISA technique to determine TNF-α concentrations and western blot technique to quantify GFAP protein expression.
We found a significant increase of TNF-α in the lungs after acute 1 ppm O_3 exposure, high levels remain after chronic O_3 exposure. While in brain, both the TNF-α and GFAP increase since the acute exposition and remain until chronic O_3 exposure. The cytokine TNF-α has been related to changes in the sleep pattern and related neurotransmitters in sleep studies and the GFAP is

considered a marker of activated glial cells during brain inflammation. Then, we postulate that such sleep changes produced by O_3 exposure could be due to the inflammatory response of the CNS.

Title: Inhibition of nitrodative-inflammatory cascade in experimental paradigm of quinolinic acid -induced neurotoxicity: Neuroprotective profile of sesamol and quercetin

Authors: *A. KUHAD, S. SINGLA, V. ARORA, K. CHOPRA;
Panjab Univ., CHANDIGARH, India

Abstract: Quinolinic acid (QA), a well known excitotoxin that produces a pharmacological model of Huntington's disease in rats and primates, has been shown to evoke degenerative events in nerve tissue via NMDA receptor overactivation and oxidative stress to exert its neurotoxic actions. Thus the affiliation of QA induced oxidative stress induced neuroinflammtory cascade represents a rational to investigate the neuroprotective role of naturally occuring antioxidants like sesamol and quercetin in the experimental paradigm of Huntington's disease. Rats were intrastriatally administered quinolinic acid and were treated with sesamol (4, 8 and 16 mg/kg, i.p) and quercetin (25, 50 and 100 mg/kg, i.p) for 14 days before and 14 days after quinolinic acid administration, with these natural antioxidants. Results demonstrated that intrastriatal injection of QA leads to increased escape latency, impaired locomotor activity, as well as significant increase in immobility time in forced swim test, This behavioural deficit was integrated with the increased nitrodative stress markers (increased lipid peroxidation, raised nitrite concentration and depletion of endogenous antioxidants such as catalase, superoxide dismutase and reduced glutathione) along with the significant increase in the TNF-α levels in rat brain suggesting QA mediated oxidative and neuroinflammatory damage. More over intrastriatal administration of QA resulted in significant decrease in the levels of dopamine, serotonin and norepinephrine in the rat forebrain. Chronic treatment with sesamol (4, 8 and 16 mg/kg, i.p) and quercetin (25, 50 and 100 mg/kg, i.p) attenuated these behavioral, biochemical and neurochemical alterations in the rat brain and these effects were attributed to their strong

antioxidant and anti-inflammatory potential. Conclusively it is suggested that major features of QUIN-induced neurotoxicity are mediated by nitrodative stress induced neuroinflammation and the neuroprotective role of sesamol and quercetin should be explored further as effective agents in the management of Huntington's disease.

Title: The role of PGC1α and mitochondrial dynamics in lead-induced neurotoxicity

Authors: *A. DABROWSKA, N. HAJJI;
Hammersmith Hosp., Imperial Col. London, London, United Kingdom

Abstract: Mitochondrial dysfunction is a known contributor to many neurodegenerative conditions including Parkinson's disease (PD). Mitochondrial biogenesis, dynamics and function have all been implicated in PD. Chronic exposure to lead (Pb^{2+}) has been shown to correlate with an increased risk of PD. A mechanism mediating this effect remains unknown but existing data suggest that mitochondrial impairment and alterations of cellular calcium balance are involved. In this study I evaluated the effect of Pb^{2+} on mitochondrial biogenesis, function and dynamics in a relevant cellular model, focusing on the role of PGC1α, a transcription coactivator, a known master regulator of mitochondrial biogenesis, also implicated in PD.
N27 dopaminergic neuronal cells were exposed to a range of lead (II) acetate concentrations (5-100 μM) for 48 hours. Mitochondrial membrane potential (ΔΨm) loss and cell death were measured by flow cytometry analysis. At low Pb^{2+} concentrations (<100μM) we observed ΔΨm loss but no cell death and a dose-dependent increase in PGC1α expression. At high Pb^{2+} concentrations (≥100μM) a reduction of ΔΨm and increased cell death were observed, accompanied by a reduction of PGC1α expression. Knockdown of PGC1α rendered the cells more susceptible to lead-induced loss of ΔΨm and led to fragmentation of mitochondria, as indicated by immunostaining. Independent knockdown of each component the Fis1/Bap31 complex has a neuroprotective effect against Pb^{2+}. Given that Fis1 is a mitochondrial fission protein and Bap31 is ER-localised and they bridge the mito-ER platform for apoptosis initiation, Pb^{2+} induced neurotoxicity could be due to disruption of mitochondrial dynamics.

Title: Novel mechanism of curcumin anti-inflammatory activity and control upstream of nf-kappa b activation in brain aging and neurodegenerative disease

Authors: *Q. CHEN[1,2], P. MAITI[1], X. ZUO[1], F. YANG[1], Q. MA[1], Z. YU[2], G. M. COLE[1], S. A. FRAUTSCHY[1];
[1]Dept. of Neurol., UCLA, Los Angeles, CA; [2]Third Military Med. Univ., Chongqing, China

Abstract: Neuroinflammation is implicated in the pathogenesis of many neurodegenerative diseases of aging. Curcumin has an outstanding safety profile and pleiotropic beneficial activities in animal models of neurodegenerative and other CNS syndromes and inflammatory diseases. A large subset of beneficial effects derive from curcumin's anti-inflammatory properties attributed to inhibition of NF-κB regulated glial activation. Further, CNS NF-κB activation appears to play an important role in regulating hypothalamic neuroendocrine changes promoting systemic aging and reducing longevity. Our previous data in multiple AD models and aged animals shows that levels of iNOS,COX2, IL-1β and TNF –α, all pro-inflammatory mediators induced by NF-κB, were suppressed in vivo by curcumin treatment with brain IC50's in the 1-2 μM range. As NF-κB is not a direct target of curcumin, the direct targets underlying NF-κB inhibition by curcumin

remain unclear. The IKK complex that sequesters NF-κB in the cytosol contains and requires CDC37/Hsp90 for its assembly so that Hsp90 inhibitors can prevent activation. Here, using GST-pull down assays, we prove that curcumin at CNS concentrations achieved in vivo directly suppresses CDC37/ Hsp90 complex formation. Complex suppression is partial and occurs below concentrations required to inhibit Hsp90 ATPase activity. We also use co-IP to show that this partial inhibition of complex formation occurs in vivo in wild type and transgenic model animals treated with curcumin. Because the CDC37/Hsp90 complex also regulates many client kinases involved in cancer and other age-related diseases, these results may help explain the remarkable pleiotropic protective activities of curcumin. The concentrations required for human CDC37/Hsp90 complex inhibition can be produced in curcumin treated people. Therefore, our data provides a novel mechanism to help explain partial NF-κB inhibition and multiple protective activities of curcumin in vivo.

Title: IL-17A and IL-17RA in mouse brain: Their expression and pathophysiological analyses by AAV-mediated overexpression of IL-17A

Authors: *J. YANG[1], J. KOU[1], R. LALONDE[2], K.-I. FUKUCHI[1];
[1]Cancer Biol. & Pharmacol., Univ. of Illinois Col. of Med. At Peoria, Peoria, IL; [2]Psychology, Univ. de Rouen, Mont-Saint-Aignan, France

Abstract: Interleukin-17 (IL-17) is a proinflammatory cytokine mainly expressed by T helper 17 (Th17) cells. Recent studies, however, show that IL-17A is expressed by several different immune cell types and that its receptor (IL-17R) is expressed in many cell types including epithelial cells, endothelial cells, fibroblasts and myeloid cells. Particularly, IL-17 is increasingly drawing attention as a crucial factor in inflammatory disorders of the nervous system. Additionally, the signaling pathways of IL-17 are being considered as therapeutic targets of such

diseases including multiple sclerosis, stroke, and brain tumors. Therefore, we have studied expression of IL-17A and IL-17RA in the brains from C57BL/6 mice at 1 and 10 months of age. Expression of IL-17A was studied by in situ hybridization with RNA oligonucleotide probes and IL-17RA expression was determined by both immunohistochemistry and western blot analysis. IL-17A expression was found in the motor cortex, priform cortex, CA1 field and granular layer of the hippocampus at 1 and 10 months of age. IL-17RA was barely expressed in the brain at 1 month and strongly expressed in the CA2 and CA3 fields of the hippocampus and the thalamus at 10 months. To further investigate the functions of IL-17A, we produced recombinant adeno-associated virus serotype 5 (rAAV5) encoding mouse IL-17A and injected the virus into the right lateral ventricle of the mouse brain. Three months after injection, high expression of IL-17A was found throughout the hippocampus and partly in the neocortex in both brain hemispheres. We are currently studying the effects of IL-17A overexpression on physiological functions, gene expression and inflammation in these experimental animals.

Title: Developing an animal model of fatigue: Neuroinflammation by pro-inflammatory cytokines

Authors: *D. BONSALL, G. B. MCKAY-CORKUM, P. C. MOLYNEUX, M. E. HARRINGTON;
Smith Col., Northampton, MA

Abstract: Fatigue is a debilitating symptom prevalent in many disease states including Multiple Sclerosis, Parkinson's disease and Chronic Fatigue Syndrome. The cause of fatigue remains unclear, however, neuroinflammation has been strongly implicated in its development. Here we present our current progress in building an animal model of fatigue that is instigated through the actions of the pro-inflammatory cytokine Interleukin 1-beta (IL-1β). Peripheral administration of IL-1β is able to significantly reduce running wheel activity in middle-aged (6-12 months old) C57Bl/6 female mice while general locomotor activity remains unaltered. Furthermore, we do not observe weight loss or fever associated with this treatment, as determined through the use of

abdominal telemetry probes. We demonstrate dose-, gender- and age-dependent differences in the response to IL-1β given peripherally. In addition, intracerebroventricular administration of IL-1β supports a centrally mediated mechanism which is explored further using immunohistochemistry. We assess IL-1β-related changes in microglial activation and in the expression of pro-inflammatory cytokines throughout the brain, in regions linked to the arousal system and motivational pathways.

Title: Loss of CA3 pyramidal neurons in mice deficient for SCYL2, a clathrin coated vesicle-associated protein pseudokinase

Authors: *S. PELLETIER[1], S. GINGRAS[1], S. HOWELL[2], L. EARLS[3], R. SMEYNE[3], S. ZAKHARENKO[3], J. N. IHLE[2];
[1]Immunol., [2]Biochem., [3]Developmental Neurobio., St. Jude Children's Res. Hosp., Memphis, TN

Abstract: SCYL2/CVAK104 is a clathrin coated vesicle (CCV)-associated protein pseudokinase of unknown function. Using biochemical, cell biological and genetic approaches, we show here that SCYL2 is an evolutionarily conserved protein that interacts specifically with the clathrin/AP2 complex and plays a critical role for the normal development and function of the nervous system and for suppressing excitotoxicity during synaptogenesis. Ubiquitous and neural-specific deletion of *Scyl2* in mice caused severe neurological disorders that resulted in the death of a majority of newborn mice. In surviving animals, SCYL2 loss caused growth retardation and symptoms of neurological disorders that were associated with the loss of various neuronal populations, most notably the CA3 pyramidal neurons of the hippocampus. Loss of CA3 neurons

occurred rapidly during the early postnatal development and was the result of an apoptotic process that was reversed by *Bax* deficiency or glutamate receptor antagonism. Ubiquitin-neurotransmitter receptor-positive aggregates and abnormal neurotrophin receptor localization in the CA3 region of the hippocampus were conspicuous. Strikingly the phenotypic changes observed in *Scyl2*-deficient mice is similar to those found in mice deficient for components of the Endosomal Sorting Complexe Required for Transport (ESCRT)-0, a protein complex required for endosomal sorting of endocytosed receptor, suggesting that SCYL2 may act along this pathway. Consistent with this, Affinity purification, biochemical fractionation and microscopic studies revealed that SCYL2 is a clathrin/AP2-associated protein that localizes pre- and post-synaptically and facilitates clathrin-mediated endocytosis and degradation of membrane receptors. Given the role of neurotrophin and neurotransmitter receptors in regulating neuronal cell death and survival, loss of CA3 neurons in *Scyl2*-deficient mice may result from their inadequate regulation.

Title: Astrocyte activation in white matter injury associated with cardiopulmonary bypass in a mouse brain slice model

Authors: K. AGEMATSU[1], L. KOROTCOVA[2], V. GALLO[2], N. ISHIBASHI[2], *R. A. JONAS[2];
[1]Children's Natl. Med. Ctr., Washington, DC; [2]Children's Natl. Med. Ctr., WASHINGTON, DC

Abstract: White matter (WM)
injury is common after cardiac surgery in neonates and young infants with severe/complex congenital heart disease (CHD). The cellular mechanisms that govern the ***response*** of the brain to surgery-induced WM injury remain largely unexplored. We studied WM astrocytes in a rodent brain slice model of brain injury caused by cardiopulmonary bypass (CPB). The

GFAP-GFP mouse was used to identify WM astrocytes. Living brain slices of postnatal day 11 mice, developmentally equivalent to the human newborn, were transferred to a closed chamber perfused with artificial cerebrospinal fluid under controlled temperature/oxygenation to reproduce conditions of CPB. After cooling to 15, 25, and 35^{o}C, 60 min oxygen-glucose deprivation (OGD) was performed to simulate circulatory arrest. An increase in WM caspase3^{+} cell number at 20hrs after reperfusion was identified in all OGD groups, including 15^{o}C ($p<.001$), but not in Control.
The number was positively correlated with temperature during OGD (rho=.66, $P<.01$), demonstrating that temperature-dependent WM injury is similar to that seen in large animal models of CPB. Caspase3^{+} astrocytes significantly increased at 20hrs after 25 and 35^{o}C OGD ($p<.001$), but not in 15^{o}C OGD, indicating that deep hypothermic OGD did not induce astrocyte injury. When the relation between astrocytes and WM apoptosis was investigated under hypothermia at 15^{o}C and 25^{o}C, GFAP^{+} astrocyte number was positively correlated with caspase3^{+} cell number at 20hrs after reperfusion ($r=.77$, $p<.001$). This finding demonstrates that astrocytes play an important role in WM injury associated with CPB using hypothermia. Therefore, future studies will target the molecular and cellular interaction between WM astrocytes and damaged cells with the goal of developing a novel pharmacological approach for reducing the risk of WM injury during cardiac surgery.

Title: Single cell imaging identifies toxic effects on functions relevant for neuronal communication

Authors: J. SISNAISKE, V. HAUSHERR, C. VAN THRIEL, *N. SCHOEBEL;
IfADo-Leibniz Res. Ctr. for Working Envrn. and Human Factors, Dortmund, Germany

Abstract: Neurons form delicate networks of interconnected cells whose communication requires intact neurites and a finely-tuned interplay of neurochemical processes at the synapse.

Because of their highly specialized morphological and functional features, neurons are especially vulnerable to the harmful effects of environmental and occupational toxins. Neurotoxicology is challenged with the need for sensitive animal-free in vitro assays to identify and estimate the neurotoxic potency of a plethora of chemicals. Typically, cell viability assays are used to evaluate neurotoxic effects in vitro. However, it has been shown that neurite degeneration may occur at concentrations that do not or only weakly affect the viability of neuronal cells. Thus, the outcome of cell viability assays may underestimate the neurotoxic potency of a given substance. Following the notion that some toxins specifically affect neurites, we evaluated whether processes critical for inter-neuronal communication might also be more sensitive to toxin treatment than cell viability. Here, we assessed the functionality of neurochemical processes by fluorescence-based optical imaging (calcium imaging) of primary cortical neurons of mice in vitro. After pretreatment with substances of different neurotoxic potential, functional responses to depolarization and glutamate stimulation were assessed. For the direct comparison of assay sensitivities, neurons were subjected to a cell viability assay (cell titer blue, CTB) in parallel. We compared the dose-response functions for toxic effects measured by both assays. For a first group of substances encompassing known non-neurotoxins (e.g. mannitol), dose-response functions and EC50 values of the functional imaging data paralleled that of the CTB. For a second group of substances including known neurotoxins (e.g. MPP+), dose-response functions obtained by functional imaging were shifted to the left by one to several orders of magnitude in comparison to the CTB. These results clearly indicate a higher sensitivity of neuronal functional parameters to certain neurotoxins than cannot be achieved by CTB. Furthermore, we suggest that the proper estimation of in vitro neurotoxic effects requires multiple test assays, with calcium imaging being a useful tool for the identification of neurotoxic effects on parameters relevant for neuronal communication.

Title: Sigma-1 Receptor Chaperone plays an essential role in neuronal function by regulating p35/CDK5

Authors: *S.-Y. A. TSAI[1], N. R. KLAUER[2], T.-P. SU[1];
[1]Cell. Pathobiology Sec Integrative Neurosci. Br,, NIDA-IRP, NIH, BALTIMORE, MD; [2]Univ. of Minnesota Med. Sch., Minneapolis, MN

Abstract: The endoplasmic reticular protein sigma-1 receptor (Sig-1R) is a novel molecular chaperone and has been implicated in central nervous system diseases such as Alzheimer's disease, depression, and drug abuse. Imaging studies have demonstrated patients with either Alzheimer's or Parkinson's disease exhibit reduced Sig-1R protein levels. Sig-1Rs are particularly enriched in the mitochondria-associate ER membrane (MAM); however, little is known about Sig-1R's specific role in neurodegeneration. This study examined the effects of Sig-1R on the regulation of the cyclin-dependent kinase (CDK)5 activator, p35. CDK5 hyperactivity has long been associated with the etiology of neurodegenerative disease due to its role in tau phosphorylation and subsequent aggregation. Neuronal damage results in release of Ca^{2+} into the cytoplasm activating the calpain protease which cleaves p35 into a more potent CDK5 activator, p25. Due to the detrimental effects of CDK5 hyperactivity, the expression of p35 is tightly regulated and exhibits a short half-life of approximately 20 minutes. Therefore, we explored specifically the role of Sig-1R in p35 degradation. Our initial results indicated that Sig-1R KO mice exhibited elevated p35 and phosphorylated tau expression. We found that this alteration in basal protein p35 expression is likely due to a reduced basal degradation rate of p35 in siSig-1R treated cells. Furthermore, upon calcium induced calpain activation, Sig-1R KO brain homogenates also displayed elevated p25 accumulation. siSig-1R neurons also exhibited increased CDK5 activity following glutamate insult. Together, these results suggest that Sig-1R is involved in the degradation of p35, which may explain the increased susceptibility of Sig-1R deficient cells to neurotoxic insults.

Title: Effects of soluble epoxide hydrolase inhibitor on NMDA-induced excitotoxicity and BDNF expression in cortical neurons

Authors: *Y.-M. KUO[1,2], T.-S. LEE[1,3], Y.-H. LEE[1,3];
[1]Dept. and Inst. of Physiology, Natl. Yang-Ming Univ., Taipei City, Taiwan; [2]Dept. of Anesthesiol., Taipei Veterans Gen. Hosp. and Natl. Yang-Ming Univ. Sch. of Med., Taipei, Taiwan; [3]Brain Res. Center, Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Soluble epoxide hydroxylase (sEH) is a dual activity enzyme with the C-terminal hydrolase activity mediating metabolic degradation of arachidonic acid into epoxyeicosatrienoic acids (EETs). Pharmacologic inhibition and genetic deletion of sEH have been shown to reduce infarct size after experimental stroke. The neuroprotective effect of sEH inhibitor was attributed to its anti-inflammatory effect, but how its direct effect on neuronal sEH contributes to the neuronal survival remains unclear. The present study investigated the effect of sEH inhibition on excitotoxicity-induced neuronal death and neurotrophic factor expression in primary cortical neurons. We used 9-10 days in vitro primary cortical neuron cultures derived from E17 rat brains. The C-terminal sEH inhibitor 12-(3-adamantan-1-yl-ureido)-dodecanoic acid (AUDA, 10μM) was used to pretreat the culture prior to the 24h NMDA treatment. Neuronal death was determined by lactic dehydrogenase (LDH) release assay, and viability was determined by WST-1 assay. Brain-derived neurotrophic factor (BDNF) mRNA expression was measured by quantitative RT-PCR. The results show that 10μM AUDA pretreatment significantly enhanced 20 and 50μM NMDA-induced LDH release, which was in accordance with results obtained in the viability assay by WST-1 assay. Real-time PCR analysis revealed that AUDA also enhances 20 and 50μM NMDA-induced BDNF mRNA expression. Thus, inhibition of the neuronal sEH hydrolase activity by AUDA seems to enhance NMDA receptor mediated excitotoxicity and BDNF expression. Of note, inhibition of sEH might counteract its anti-inflammation-dependent neuroprotection when applied to brain injuries involving excitotoxicity-induced neurodegeneration.

Title: Perturbation in the miRNA gene regulation associated with neurodegeneration and neurogenesis

Authors: *A. CHOUDHARY, R. ROSHAN, K. SONI, A. R. SINGH, S. SHRIDHAR, R. DEY, S. SIVASUBBU, B. PILLAI;
Inst. of Genomics and Integrative Biol., New Delhi, India

Abstract: Spinocerebellar ataxia 17(SCA17) is a type of polyglutamine disease characterized by CAG repeat expansions near the N-terminus of the general transcription factor, TATA Binding Protein (TBP). Expansion of the polyglutamine repeat in TBP increases its propensity to form aggregates in neuronal cells and leads to the gradual death of neurons causing ataxia, dementia and involuntary movements in the patients. To understand the molecular mechanisms involved in the pathogenesis of SCA17, we have created and validated a cellular model by expressing human TBP with normal and expanded glutamine repeats in Neuro2A cells. Using gene expression analysis we have earlier shown several differentially expressed miRNAs in neuronal cells undergoing apoptosis due to the expression of the mutant TBP. We predicted the putative targets of these miRNAs and experimentally validated a set of calcium signalling genes as target genes including Inositol triphosphate receptor1 (ITPR1), Syntaxin1a (STX1A) and AKT3. These genes contribute in neuronal calcium signalling and neurotransmitter release and hence are important in the context of neurodegeneration. Also, in the mRNA expression profiles we found a set of differentially expressed mRNAs which are involved in the IFNϒ signalling pathway. We also observed that IFNϒ can regulate the expression of miRNAs in both STAT1 dependent or STAT1 independent manner and thereby regulate the cellular targets of miRNAs. Integrating mRNA and miRNA gene expression profiles, we are able to demonstrate a novel mRNA- miRNA interaction network that plays important role in cellular model of neurodegeneration.
We also emplyoed a zebrafish based model to study neurogenesis. We have studied the effect of several miRNAs on the zebrafish brain development. Interestingly,knockdown of miR-34a ,a cell cycle regulator and modulator of notch signalling pathway resulted in the defects in the early development of hindbrain of zebrafish. Phenotypes of knockdown of other miRNAs during zebrafish development are also discussed.

Title: Dopamine transporter (DAT) expression in the medial prefrontal cortex and striatum of Long-Evans rats is affected by perinatal exposure to polychlorinated biphenyls

Authors: M. M. MILLER, J. L. NELMS, A. E. MEYER, *H. J. SABLE;
Dept. of Psychology, Univ. of Memphis, Memphis, TN

Abstract: Due to their persistence and ubiquity in the environment as well as their current presence as an unintentional byproduct of manufacturing, polychlorinated biphenyls (PCBs) assert a significant human health threat. Modifications in brain dopamine (DA) concentrations following perinatal exposure to PCBs in rats have been shown to persevere into adulthood, and we have demonstrated perinatal PCB exposure alters the behavioral response to psychostimulant drugs known to act on the DA system during adulthood. Previous findings demonstrate that adult exposure to PCBs inhibits DAT expression, but the effects on DAT following perinatal exposure are less understood. The purpose of this project was to determine the effects of prenatal and early postnatal exposure to an environmentally relevant mixture of PCBs on DAT expression in the medial prefrontal cortex (mPFC) and striatum in weanling rats. Long-Evans dams were orally exposed to 0, 3 or 6 mg/kg/day of an environmentally relevant mixture of PCBs beginning at 4 weeks prior to breeding and continuing until litters were weaned on postnatal day 21. At weaning, the mPFC and striatum were extracted from one male and one female per litter for Western blot analysis. It was hypothesized that DAT expression in animals exposed to PCBs during the perinatal period would be reduced relative to non-PCB-exposed control rats. Results confirmed the hypothesis and demonstrated that weanlings exposed to 6 mg/kg/day PCBs had less DAT expression compared to rats in the 3 mg/kg/day group and non-PCB-exposed control group in both mPFC and striatal samples. These findings indicate that perinatal exposure to an environmentally relevant PCB mixture results in an outcome similar to what has been reported in adult animals exposed to PCBs, and suggest a possible mechanism for the differential response to psychostimulant drugs observed in rats perinatally exposed to PCBs.

Title: Differential functions of infiltrating macrophages and resident microglia after spinal cord injury

Authors: *A. D. GREENHALGH, S. DAVID;
McGill Univ., Montreal, QC, Canada

Abstract: Macrophages in the injured spinal cord arise from resident microglia and infiltrating, peripherally derived monocytes. It is still not clear if macrophages derived from these two populations differ in their roles after spinal cord injury (SCI). The aim of this study was to investigate the contribution to the phagocytic response and the clearance of damaged axons by macrophages derived from resident microglia in comparison to macrophages of a peripheral, blood-borne origin. The LysM-eGFPki transgenic mouse tags haematogenous macrophages, but not microglia, and allows the study of these two previously indistinguishable cell populations without the need for chimeric experiments. We used a combination of immunofluorescence, flow cytometric and neuronal tracing techniques (using fluorescently labelled dextran to trace axons in the dorsal column) we show that microglia contact damaged axons early (24 h) after SCI and are the predominant type of macrophage to contain phagocytic material at 3 days. Thereafter, infiltrating macrophages become the predominant cell in contact with degenerating axons and contain more phagocytic material. Furthermore, after phagocytosing myelin in vitro, bone marrow derived macrophages are much more susceptible to apoptotic and necrotic cell death than CNS microglia. These data show that peripherally derived macrophages are the main cell type to phagocytose degenerating axons after CNS injury despite the presence of microglia, but may not be as well equipped to process the phagocytosed material. Overall, these data highlight the differential roles played by different types of macrophages, depending on their origin, and provide further information for cell specific targeting of inflammatory response after SCI.

Title: The role of microRNAs (miRNAs) in the inflammatory processes related to ageing: A pilot study

Authors: *A. M. FLOREA;
Dept. of Envrn. Toxicology, Univ. of Trier, Trier, Germany

Abstract: Chronic inflammation is an important phenomenon that takes place in the ageing processes of the brain. MiRNAs are gene regulators that play a role in post-transcriptional repression of many genes. A new body of evidence shows that miRNA are able to property finely-tune gene expression of genes that are important for immune system regulation (Olivieri et al., 2013) thus, the precise control for proper activity if immune response could be affected. For instance the expression of hsa-miR-21 was associated with ageing in humans which in turn is a validated target of the TGF-βR2 mRNA that is as well deregulated in inflammatory processes related to ageing. Thus, miR-21 may represent a new biomarker of inflammation (Olivieri et al., 2012; 2013). Also in vitro cellular senescence has been associated with inflammatory response and miRNA deregulation (e.g. miR-21, miR-214, miR-92; Rippe et al., 2012). In this study we investigate the involvement of miRNAs in ageing related inflammatory processes with a focus on the brain. Literature and data mining are used together with own investigation in order to underline new prove of evidence supporting the hypothesis. Olivieri et al., 2013; doi: 10.1186/1742-4933-10-11.Olivieri et al., 2012; doi: 10.1016/j.mad.2012.09.004. Rippe et al., 2011; doi: 10.1016/j.exger.2011.10.004.

Title: Effects of cytidine 5′-diphosphocholine (CDP-choline) on hypoglycemia-induced neuron death

Authors: *J. KIM[1], B. CHOI[1], H. KIM[1], J. YOO[1], M. SOHN[2], H. CHOI[1], H. SONG[1], S. SUH[1]; [1]Dept. of Physiol., Hallym University, Col. of Med., Chuncheon, Korea, Republic of; [2]Inha Univ., Incheon, Korea, Republic of

Abstract: Diabetic patients who attempt strict management of blood glucose levels frequently experience hypoglycemia. Severe and prolonged hypoglycemia causes neuronal death and cognitive impairment. There is no effective tool for prevention of these unwanted clinical sequelae. Citicoline (CDP-choline; cytidine 5'-diphosphocholine) is an important intermediate in the biosynthesis of cell membranes phospholipids. Citicoline serves as a choline donor in the metabolic pathways for biosynthesis of acetylcholine and neuronal membrane phospholipids, mainly phosphatidylcholine. The ability of citicoline to reverse the neuronal injury has been tested in animal models of cerebral ischemia and also has been performed clinical trial in stroke patients. However, no previous report has examined the effect of citicoline on hypoglycemia-induced neuron death. To clarify the therapeutic potency of citicoline on hypoglycemia-induced neuron death, we used an animal model of insulin-induced hypoglycemia. Acute hypoglycemia was induced by intraperitoneal injection of human insulin (10 U/kg), and then iso-electricity was maintained for 30 minutes. Citicoline injection was started immediately after hypoglycemia (500mg/kg, i.p.). ROS production was evaluated at 3 hours after hypoglycemia. Neuronal injury, microglia activation and BBB disruption were evaluated at 1 week after hypoglycemia. Here we found that post-treatment of citicoline showed significant less ROS production, neuron death, microglia activation and BBB disruption in the hippocampus compared to vehicle treated group. Taken together, these results suggest that neuronal membrane stabilization by citicoline can rescue neurons after severe hypoglycemia as seen in several ischemia studies. The present study suggests that citicoline may have a high therapeutic potential to reduce hypoglycemia -induced neuronal death.

Title: Neuroinflammation: pathological mechanisms and the beneficial role of insulin therapy

Authors: *L. ADZOVIC[1], S. C. HOPP[2], R. M. KAERCHER[1], S. E. ROYER[2], H. M. D'ANGELO[2], G. L. WENK[1];
[1]Dept. of Psychology, [2]Neurosci., Ohio State Univ., Columbus, OH

Abstract: Chronic neuroinflammation is associated with many neurodegenerative diseases such as Alzheimer's and Parkinson's diseases. It produces an elevation of pro-inflammatory cytokines, an impairment of spatial memory or motor function and a dysregulation of diverse neurotransmission in selectively vulnerable brain regions. The role of insulin receptor (IR) in the brain is still not clear and several studies suggested it may have a neuroprotective function. Our work analyzed if insulin has a role in neuroprotection by preventing the neuroinflammatory response to lipopolysaccharide (LPS). In this study, we investigated the time course of behavioral, biochemical and pathological changes relative to different brain regions including the hippocampus, substantia nigra and locus coeruleus following either experimentally induced chronic neuroinflammation or neuroinflammation associated with normal aging. Neuroinflammation was created by infusing LPS continuously for four weeks into the 4th ventricle of young (3 months) rats. The neuroprotective actions of insulin were investigated. All rats underwent behavioral testing (Morris water maze, MWM and forced swim, FS). Afterwards, the hippocampus and brainstem were examined by immunohistochemistry the evidence for cell loss (NeuN, GFAP and Caspase-3) and by qRT-PCR to determine gene expression of TNF-α, IL-1ß, IL-10, TGF-ß, TLR4, PPARy, BDNF and GLT1. The results showed that young and middle-aged rats exposed to LPS performed poorly in the MWM as compared to the controls; all aged rats were impaired in MWM task. The gene expression of pro- and anti-inflammatory markers varied depending on the presence of LPS or insulin and the age of the rat.

Title: Baseline PAG cerebral blood flow predicts pain phenotype in a healthy human model of central sensitisation

Authors: *M. MEZUE, V. WANIGASEKERA, M. KELLY, M. CHAPPELL, I. TRACEY; Nuffield Dept. of Clin. Neurosciences, Univ. of Oxford, Oxford, United Kingdom

Abstract: The periaqueductal grey (PAG) has been implicated in descending pain modulatory processes in humans and is thought to be involved in bi-directional pain control. Previous studies have shown the importance of the PAG and other brainstem structures in the maintenance of central sensitisation via descending connections with dorsal root ganglion cells in the spinal cord. Here, we use a novel arterial spin labelling (ASL) fMRI approach and a model of central sensitisation to investigate the importance of inter-individual differences in PAG perfusion at baseline, and its relationship to pain vulnerability in a healthy population.

Method

20 healthy subjects were scanned in two separate sessions in a 3T Verio MRI scanner. In the first session (BL), a 10 minute baseline perfusion fMRI scan (pseudo-continuous ASL, 5 inversion times) was taken, with subjects in a non-sensitised state. In the second session (CS), subjects were scanned 90 minutes after 1% capsaicin cream had been applied on the right leg.

Image analysis was performed with FSL tools. Absolute cerebral blood flow (CBF) was calculated by using a Bayesian inference tool (BASIL) to iteratively calculate blood magnetization kinetics across all voxels for each TI. CBF values were extracted from PAG voxels (for each subject's BL session).

Ongoing and evoked pain scores were evaluated using visual analogue. In the sensitised state, a hyperalgesia score was defined by taking the difference between subject ratings of perceived unpleasantness to elicited punctate stimuli (512 mN probe) before and after capsaicin application.

Results

In the CS session, subjects reported (mean[/100] ±SD) ongoing pain of 18.3 ±11.4 and developed punctate unpleasantness hyperalgesia of 28.3 ±18.1.

Baseline PAG perfusion correlated strongly with ongoing pain scores (average of pre- and post-scan) ($r(18)=0.53$, $p<0.05$) and with punctate hyperalgesia scores ($r(18)=0.53$, $p<0.01$).

We also show that inter-individual baseline PAG CBF values correlate with decreases in perfusion in the CS state (compared to BL) in the contralateral hypothalamus, hippocampus, amygdala and bilateral insula (whole-brain cluster corrected: $Z>2.3$, $p<0.05$).

Discussion

We show that CBF in a key nucleus of the descending pain system predicts individual behavioural and neural responses in the central sensitised state. This positive correlation may indicate that individuals with more facilitatory drive from the PAG at baseline are more vulnerable to pain in an injured state. Furthermore, these individuals may also exhibit increased brainstem plasticity leading to decreased PAG inhibition and hypoperfusion of connected subcortical areas in the CS state.

Sch. of Med., New Haven, CT; [9]Dept for ansesthesiology, Univ. of Heidelberg, Mannheim, Germany

Abstract: Patients with distal limb pain carrying a diagnosis of erythromelalgia (EM) were investigated by microneurography to record action potentials from unmyelinated nerve fibers (C-units) in cutaneous fascicles of the peroneal nerve. Three patients had mutations in sodium channel (NaV) 1.7 (I848T, I228M, P187L) while no mutations of coding regions of NaVs were found in 4 EM patients.
Recorded C-fibers were classified according to responsiveness to von Frey stimulation (75 mN) and activity-dependent conduction velocity slowing (ADS). ADS and excitability changes following single action potentials (recovery cycles) were tested in single fibers with electrical stimulation in their cutaneous receptive field.
In the patient with mutation I848T all mechano-sensitive C-nociceptors (CM) were characterized by activity-dependent speeding of conduction rather than ADS. In contrast, sympathetic fibers showed the expected ADS. In the recovery cycles, the mechano-sensitive C-fibers had an early subnormality that changed into supranormal conduction around 700 ms after the preceding action potential.
In contrast, no differences in ADS or recovery cycles were found in CM nociceptors between EM patients without mutations, with mutations I228M and P187L, and healthy controls. Irrespective of NaV1.7 mutations, in the EM patients about 30-50% of the fibers showed

spontaneous activity which could be evoked by heating the skin of the receptive field in some fibers. In these patients, only the atypical afferent C-fibers with spontaneous activity and/or mechanical sensitization showed signs for a more moderate depolarization in the recovery cycles.
Our data suggest a massive axonal depolarisation in the patient with I848T mutation which corresponds to patch clamp data and the severe clinical symptoms of the patient. In the patients with other NaV1.7 mutations, no such specific changes could be observed. However, there were signs of moderate depolarisation in hyperexcitable nociceptors in the patients with and without NaV1.7 mutations (I228M, P187L).
Using microneurography, we find a generic pattern of hyperexcitability in EM patients and changes suggestive of axonal depolarization irrespective of NaV1.7 mutations. Mutation specific changes were restricted to the clinically most severe case of EM with I848T mutation.

Title: Proteins increased in cerebrospinal fluid after spinal cord stimulation elucidate human neuropathic pain relief mechanisms

Authors: LIND[1,2], M. SJÖDIN[1], L. KATILA[2], M. WETTERHALL[1], T. GORDH[2];
[1]Dept. of Analytical Chem., Uppsala, Sweden; [2]Dept. of Surgical Sciences, Uppsala Univ., Uppsala, Sweden

Abstract: Objective: To elucidate the analgesic mechanism of spinal cord stimulation (SCS) in patients with neuropathic pain.
Introduction: SCS is a treatment option available to some patients with otherwise treatment resistant neuropathic pain. More than 50% pain relief is obtained during SCS trial stimulation for 60-70% of the patients. Though successfully used since the 1960s, the analgesic mechanism of SCS in neuropathic pain remains unknown. For responders, SCS is in many respects an ideal treatment. However, it is not known why 30-40% of patients do not respond. Also, SCS is initially costly, and rather work intensive as it includes trial stimulation, surgery, battery changes and in some cases lead migration correction surgery. Understanding of the mechanism of SCS analgesia in neuropathic pain could lead to further improvements of current treatments of neuropathic pain and reveal previously unknown therapeutic targets directly in patients with successful treatment. It is plausible that the cerebrospinal fluid (CSF) mirrors parts of mechanism relevant molecular changes taking place in the CSN during stimulation.
Methods: CSF samples were collected from SCS-responsive neuropathic pain patients (n=12) at two separate occasions, first after the SCS had been turned off for 48 h, and then after the SCS had been used normally for three weeks. The off- and on-state proteomes for each patient were relatively quantified using a mass spectrometry shotgun proteomic approach.
Results: A panel consisting of seven proteins, 5 up-regulated (angiotensinogen, kallikrein-6 , amyloid beta A4 protein A4, ganglioside GM2 activator SAP3 and Ly-6/neurotoxin-like protein 1) and 2 down-regulated (complement C2, insulin-like growth factor-binding protein 6)was found to be significantly altered ($P \leq 0.01$) by pain relieving SCS in humans.
Conclusions: This is to our knowledge the first assumption-free longitudinally designed proteomic study of CSF from neuropathic pain patients using SCS. Our findings are unexpected and open several novel research questions about the therapeutic mechanism of spinal cord stimulation.

Title: Gamma oscillations in the somatosensory thalamus of a phantom limb patient

Authors: *D. BASA[1,2], M. HODAIE[3], A. LOZANO[2], W. D. HUTCHISON[2];
[1]Univ. of Toronto, Toronto, ON, Canada; [3]Neurosurg., [2]Toronto Western Hosp., Toronto, ON, Canada

Abstract: Phantom limb is the abnormal perception of a non-existent extremity that occurs in patients who have undergone accidental or clinical amputation of a limb. Thalamocortical dysrhythmia (TCD) has been proposed as a model to explain the intrinsic generation of this percept. TCD refers to the abnormal occurrence of theta-gamma oscillations in deafferented areas of the thalamus. We report the occurrence of gamma oscillations (37Hz) in the somatosensory (ventral caudal - Vc) thalamus of a phantom limb patient whose right arm was amputated at the shoulder. Microelectrode recordings were obtained from 3 patients (phantom limb, post-stroke pain and essential tremor) during surgical targeting procedures for deep brain stimulation implants. A total of 22 ventral caudal (Vc - sensory) and 21 ventral intermediate (Vim - motor) cells were analyzed for oscillations in the gamma band in spikes and local field potentials (LFPs). Spikes were template matched using Spike2 (CED) and spectral analysis of spike trains and LFP signals was performed in MATLAB. In the phantom limb patient, 6 out of 7 sites in left Vc, had ongoing 37Hz gamma oscillatory activity in both spike train and LFPs. Gamma oscillations were strongly coherent between spikes and the LFP at these sites. Post-stroke pain and essential tremor patients showed no significant gamma oscillations in Vc. Sustained gamma oscillations in the phantom limb case were confined to Vc and did not occur in Vim. Moreover, high frequency stimulation (50 uA, 200 Hz, 2 s) at two Vc sites induced the 37 Hz gamma oscillation in both spikes and LFPs. The stimulation was concomitant with the patient's report of paresthesia in the non-existent arm. The results suggest a causal relation between pathological gamma oscillations in the somatosensory thalamus and the conscious perception of the phantom limb.

Title: Significant reduction in fibromyalgia (FM) tender point count, widespread pain index (WPI) and symptom severity (SS) score after one month of treatment with AVACEN thermal exchange system (TES)

Authors: *T. MOELLER-BERTRAM[1], M. G. KINCAID[2], R. BOOHER[3], D. GARCIA[4], L. KY[5], J. M. SCHILLING[3], I. STRIGO[2];
[1]Coastal Pain Res., Carlsbad, CA; [2]Psychiatry, Veteran Affairs San Diego Healthcare Syst., San Diego, CA; [3]Anesthesiol., [4]Univ. of California San Diego, San Diego, CA; [5]Anesthesiol., Palomar Hosp., San Diego, CA

Abstract: Fibromyalgia (FM) is a common chronic pain disorder that also affects sleep and mood. The diagnosis of FM was classically made using a tender point exam system, but the new American College of Rheumatology Diagnostic Criteria recognize the importance of quantitative measure of widespread pain (WPI) and also incorporates key FM symptoms (SS Score). The treatment of FM remains challenging, and the underlying pathology is poorly understood. Recent evidence implicates involvement of arteriovenous (AV) shunts of the extremities in FM pathology. The AVACEN Thermal Exchange Method (TEM) is a therapeutic medical device and method that manipulates AV shunts in the palm of the hand. TEM noninvasively infuses heat into the circulatory system for whole body treatment. A pilot study using TEM for 10 minutes once a day in 5 FM subjects showed reduction in FM related pain and related symptoms. In a follow up study, 17 subjects (2 male, 15 female) with physician diagnosed FM were enrolled after IRB approval and trained in the use of the TEM device. The modified protocol required use for 15 minutes twice a day for four weeks. Outcome measures included physician assessed FM diagnostic criteria including a tender point exam, WPI and SS score, and weekly self-assessed pain ratings. All assessments were carried out before (n=17) and after (n=14) the treatment period. Data were analyzed with either a paired t-test, or the Wilcoxon signed rank test depending on parametric or non-parametric distribution. Comparing the data from before and after treatment showed the following findings: 1) a significant reduction in tender point counts, 2) significant reduction in WDI score, 3) significant reduction in SS score.
These data suggest a positive effect of a one month treatment with the AVACEN TES on

Fibromyalgia pain and related symptoms. Further studies in larger cohorts are warranted.

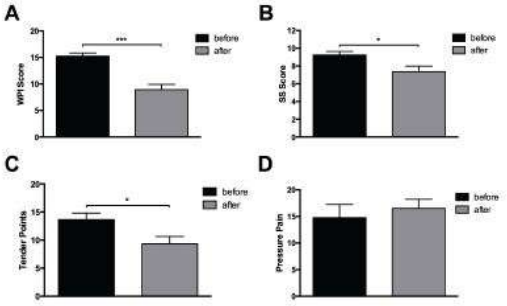

Figure 1: A significant difference was observed between timepoints (before and after) in the read-outs **(A)** Widespread Pain Index (WPI) score, **(B)** Symptom Severity (SS) score, and **(C)** Tender Points. No significant difference was observed in **(D)** Pressure Pain. Data were analyzed with either a paired t-test, or the Wilcoxon signed rank test depending on parametric or non-parametric distribution. All data are presented as Mean±SEM. Significance was assumed when *p<0.05. N (before) = 17; N (after) = 14.

Title: Disrupted functional connectivity of the periaqueductal gray in chronic low back pain

Authors: *R. YU;
HMS-MGH, Charlestown, MA

Abstract: Introduction
Non-specific chronic low back pain is a common neurological disorder. The periaqueductal gray (PAG) plays a key role in the descending modulation of pain. In this study, we investigated brain resting state PAG functional connectivity (FC) differences between patients with chronic low back pain (cLBP) and matched healthy controls (HC).
Materials and Methods:
cLBP patients (age=36.1±9.9, 6 males) and age and gender matched healthy controls were scanned with a 3T Siemens Trio TIM scanner using a 32-channel head coil. Two resting-state BOLD fMRI scans were acquired with TR/TE=3000/30 ms, 3 mm isotropic resolution and 47 slices for 6.2 min each. Before and after each resting scan, study subjects were asked to rate the intensity of their LBP using a 0-10 scale.
PAG seed based functional connectivity (FC) analysis (PAG seed coordinate x=4, y=−26, z=−14, with 2mm radius) was performed to investigate the difference between the connectivity maps in the two groups ($P<0.05$, family wise corrected (FWE) after small volume correction). The correlation between whole brain FC and self-reported spontaneous pain intensity was also computed.
Results:
18 cLBP patients and XX matched controls completed the study. Data analysis showed increased FC between PAG and medial prefrontal cortex (mPFC) in cLBP patients compared with matched controls. In addition, we also found significant negative correlations between pain ratings and PAG-globus pallidus and PAG-orbitofrontal cortex FC. The cLBP illness duration was negatively correlated with PAG-insula FC.
Discussion / Conclusion:
These findings are in line with the impairments of the descending pain modulation reported in patients with cLBP. Our results provide evidence showing cLBP patients have abnormal FC in PAG centered pain modulation network during rest.

Title: Acupuncture modulates functional connectivity in knee osteoarthritis patients

Authors: X. CHEN[1], R. SPAETH[1], F. SONYA[1], D. SCARBOROUGH[2], R. EDWARDS[3], A. WASAN[3], R. GOLLUB[1], *J. KONG[1];
[1]Psychiatry, [2]Massachusetts Gen. Hosp., CHARLESTOWN, MA; [3]Brigham and Women's Hosp., Boston, MA

Abstract: Introduction
Recent advancesin brain imaging have contributed to our understanding of the neural activity associated with acupuncture treatment. However, most acupuncture studies to date have been conducted with healthy subjects in a single treatment session, which contrasts considerably with actual clinical practice. Here, we investigated neural activity in patients with knee osteoarthritis (OA) across severalacupuncture treatments.

Methods
OA patients were randomized to receive6 treatments of high dose, low dose, or sham acupuncture. 3T resting state functional magnetic resonance imaging scans were acquired pre and post the 1st, 3rd and 6th treatments.The Knee Injury and Osteoarthritis Outcome Score (KOOS) was used to measure clinical outcomes. Resting state data were analyzed using Independent Component Analysis (ICA) in FSL.Brain connectivity was compared between real (high and low dose) and sham acupuncture groups before and after the 4weeks oftreatment.

Results
Thirty patients (10/group) completed the study. Two sample t-tests indicated no significant

differences in clinical outcome between the high and low dose groups for any of the KOOS subscales. There was a significant interaction between acupuncture mode (real vs. sham) and time(baseline vs. endpoint) for pain ($F(1,28)=5.596$, $p=.025$) and function in sport ($F(1,27)=4.252$, $p=.049$).

ICA identified multiple resting networks with connectivity changes,including the executive control network (ECN) and somatosensory network (SN). In comparing the post-acupuncture scan from Treatment 6 to the pre-acupuncture scan from Treatment 1, the real acupuncture group demonstrated stronger ECN connectivity with rostral anterior cingulate gyrus (rACC) and medial prefrontal cortex (MPFC) than the sham group after acupuncture treatment. Interestingly, in comparing the pre-acupuncture scan from Treatment 1 to the pre-acupuncturescan from Treatment 6, the SN showed reduced connectivity in dorsal ACC (dACC) after real acupuncture treatment compared to the sham group. There is a gradual change inpre-treatment resting state connectivity across treatment sessions, which suggests an additive effect of real acupuncture in reducing connectivity in the dACC.

Conclusion

We found that real acupuncture can reduce the functional connectivity between the SN and dACC, a key region involved in the affective component of pain, and increase the functional connectivity between the ECN and rACC, a key region in the descending pain modulatory network. Our results suggest that acupuncture may achieve its known therapeutic effects on chronic pain through modulating functional connectivity.

Title: Changes in low frequency oscillations in patients with neuropathic pain: A resting state fMRI study

Authors: *E. BAGARINAO, JR, I. CARROLL, N. CHATTERJEE, H. UNG, C. WANG, R. MOERICKE, S. MACKEY;
Stanford Univ., Palo Alto, CA

Abstract: Resting state functional magnetic resonance imaging is increasingly used to study neuropsychiatric disorders. In chronic pain, alterations in resting state networks, regions showing strong temporal correlation of low frequency oscillations (LFOs) across the brain, have been demonstrated in several studies [1]. In this work, we examined changes in the amplitude of these low frequency oscillations in patients with neuropathic pain (NP) compared to healthy controls (HCs). We hypothesized that neuropathic pain alters resting state LFOs in brain regions relevant to pain processing.

Resting state datasets from 28 participants (14 patients with NP and 14 age-matched HCs) were used in the analysis. The mean age is 43.43 (±14.22) years old for the NP group and 43.79 (±15.41) years old for the HC group. All participants gave informed consent prior to their participation and experimental protocols were approved by Stanford University Institutional Review Board. The functional datasets were preprocessed as follows: realigned relative to the first image in the series, co-registered to their respective anatomical image, normalized to MNI space, and smoothed using an 8mm full-width-at-half-maximum 3D Gaussian filter. The fractional amplitude of low frequency fluctuations (fALFF) within 0.01-0.08Hz was computed in all voxels, and then converted into a z-score. A two-sample t-test was used to compare the two groups. Contrast maps were cluster-corrected for multiple comparison using topological false discovery rate ($q < 0.05$).

Consistent with our hypothesis, patients with NP showed altered LFOs in regions implicated in pain modulation. Significant decreases in fALFF values were observed in right dorsal anterior cingulate cortex (dACC), left dorsolateral prefrontal cortex (dlPFC), and left anterior prefrontal cortex (aPFC) in patients with NP compared to HCs. These cingulo-frontal regions have been considered part of the descending pain modulatory pathway and play an important role in the control of pain perception. The left dlPFC, for example, has been shown to exert active control on pain perception by modulating the strength of coupling between midbrain and medial thalamus [2]. Changes in LFOs in these regions could signify alterations in this pain modulatory function in NP. Regions showing increases in fALFF values in the patient group include left occipital and lingual gyri. These findings further demonstrate the abnormalities in spontaneous brain activity observed in NP and provide additional insights into the mechanism of the functional changes involved.

Title: Evidence of decreased innervation density in multiple myeloma patients with subclinical peripheral neuropathy prior to chemotherapy

Authors: *A. KOSTURAKIS, Z. HE, H. ZHANG, P. M. DOUGHERTY;
Pain Res., MD Anderson Cancer Ctr., Houston, TX

Abstract: Preclinical studies show that chemotherapy-induced peripheral neuropathy could be due to the depletion of primary afferent sensory fibers after treatment. Recent studies indicate that disease-related processes of cancer may cause subclinical peripheral neuropathy in cancer patients prior to undergoing chemotherapy treatment. The goals of this study were 1.) to determine whether subclinical neuropathy is more prevalent than previously appreciated in a population of treatment naïve multiple myeloma (MM) patients using quantitative sensory testing (QST) analysis and 2.) to assess whether sensory deficits in patients is correlated with decreased innervation density of the extremities using non-invasive imaging. MM patients with no history of peripheral neuropathy underwent QST prior to chemotherapy. Skin temperature, sensorimotor function (grooved pegboard test) and detection thresholds for temperature, sharpness and low threshold mechanical stimuli (von Frey monofilaments and the Bumps detection test) were measured. Meissner's corpuscle (MC) density in the fingertips was assessed using *in vivo* laser reflectance confocal microscopy. Data from age-and sex-matched healthy volunteers was used as the control. Patients showed a high incidence of subclinical sensory deficits as demonstrated by higher thresholds of von Frey, Bumps, and warmth detection as compared to healthy volunteers. Patients also showed increases in cold pain, sensorimotor deficits, and higher overall neuropathy scores. MC density was significantly lower in patients compared with healthy volunteers and showed significant inverse correlation to Bumps detection threshold. Taken together, MM patients commonly present with sensory and sensorimotor deficits prior to undergoing chemotherapy treatment and these deficits appear to be correlated with a disease-related decrease in peripheral innervation density.

Title: Multiple synaptic vesicle-associated proteins colocalize in mechanoreceptors and free nerve endings in skin

Authors: *B. D. MCADAMS[1], G. WENDELSCHAFER-CRABB[2], W. KENNEDY[2];
[1]Dept Neurol., Univ. Minnesota Neurosci Prgm, Minneapolis, MN; [2]Dept Neurol., Univ. Minnesota, Minneapolis, MN

Abstract: Synaptic vesicle proteins are critical for normal chemical neurotransmission. Synaptic proteins have been detected in cutaneous Merkel cells and in neuromuscular junctions in the peripheral nervous system (McAdams et al., 2011). In this study, we describe the distribution of presynaptic proteins in human cutaneous nerve fibers that are critical for sensory and neuroendocrine functions in skin. Peripheral nerve fibers were localized by immunostaining human skin with neural-specific PGP9.5/UCHL-1 and βIII-tubulin. In epidermal nerve fibers, SV2 and synaptophysin expression often was greatest in the most superficial endings in the stratum spinosum where the local gradient of extracellular calcium is highest. Although present in epidermal cells of the stratum basale, synaptotagmin 1 was not detected in the epidermal nerve fibers. Synaptotagmin-1 and VGLUT1, a presynaptic vesicular glutamate transporter, were, like SV2 and synaptophysin, strongly immunoreactive in two mechanoreceptive nerve structures of glabrous skin, the Meissner's corpuscles and Merkel cells. This suggests a neurosecretory function in these mechanoreceptors which includes glutamate release. Potential synaptic contacts in Merkel cells and Meissner's corpuscles were identified by dense clustering of mitochondria which colocalized with presynaptic protein immunostaining. Nerve fibers to sweat glands and blood vessels also co-expressed SV2, synaptophysin and synaptotagmin-1, but not with VGLUT1. Finally, while epidermal and dermal nerve fibers immunostained for the scaffolding protein ankyrinB, as demonstrated previously (Engelhardt et al., 2012), resident Schwann cells and adjacent nerve fibers of the Meissner's corpuscle were immunopositive for ankyrinB. These results confirm that synaptic vesicle proteins are present in cutaneous nerve fibers including in mechanoreceptors. A potential autocrine or paracrine role in neuromodulatory signaling of these cutaneous fibers may explain the localization of these synaptic proteins in cutaneous nerve. Future research on the function of these proteins in cutaneous neurons could provide clinically relevant biomarkers for molecular diagnosis of peripheral sensory neuropathies, such as those afflicting patients with diabetes and cancer.

Title: Fibromyalgia patients and healthy controls show differing cortical activation patterns during the stroop task: An fMRI study

Authors: *S. MARTINSEN[1], J. BERREBI[1], P. FLODIN[1], I. VILEVICIUTE-LJUNGAR[2], M. LÖFGREN[2], M. INGVAR[1], P. FRANSSON[1], E. KOSEK[1];
[1]Clin. Neurosci., Karolinska Institutet, Stockholm, Sweden; [2]Dept. of Clin. Sciences, Danderyd Hosp., Karolinska Institutet, Sweden

Abstract: Introduction
In response to painful stimulation, a network of areas in the brain activate, including the sensory cortices, insula, thalamus and the anterior cingulate cortex (ACC). The level of activity in the ACC has been found to differ between healthy controls and chronic pain patients during nociceptive stimulation (Jensen et al. 2009), specifically; fMRI studies have shown that fibromyalgia (FM) patients show less activity in the rostral ACC (rACC) during painful stimulation. The ACC has also been found to be involved in various aspects of higher order cognitive processes, something of which FM patients report having difficulty with. Previous studies using the Stroop task (a measure of response inhibition) have found that low performers show greater activity in the ACC compared to high performers (Floden et al. 2010). Presumably this could reflect a differential degree of involvement of the ACC linked to degree of cognitive work that is required to perform the task at hand. Using the Stroop task we wanted to investigate the role of the ACC in FM for a cognitively demanding task. We hypothesized that the patient group would engage their ACC more strongly than healthy controls. Holding true, this would suggest that the ACC dysfunction seen in FM patients might be coupled to chronic pain.
Methods
15 female FM patients and 18 female healthy controls were included in the study. Participants underwent functional magnetic resonance imaging (fMRI) during which they performed two 10 minutes sessions of an event related version of the Stroop paradigm (red green and yellow written in congruent or incongruent color). Participants were given a response box with buttons

matching the colors used in the task, and they were instructed to respond to the color of the text and not to the meaning of the word presented. Image pre-processing and statistical analysis were performed in SPM8.
Results
At the within-group level we found similar activation patterns for both groups, including the inferior frontal gyrus, ACC, and superior parietal lobule. When comparing activation patterns across groups, we found that FM patients showed higher activation in the ACC (x -2, y 26, z 40, peak T value 3.25, $p<0.001$ uncorrected).
Conclusions
In line with our hypothesis, a between-group comparison showed that the FM group activated the ACC more strongly than the HC group for the Stoop task.
We interpret the stronger ACC activation for patients relative to healthy controls as an additive effect in the anterior cingulate cortex during the Stoop task. Presumably, this is related to the negative effects of chronic pain on cognitive function.

Title: Developmental trajectories of insula volume changes in adolescent anorexia nervosa

Authors: *P. A. KRAGEL, J. WANG, R. VALDOVINOS, N. L. ZUCKER, K. S. LABAR; Duke Univ., Durham, NC

Abstract: Adolescence is a key developmental period for functional and structural changes in brain regions associated with interoception and self-referential processes, including those related to psychosomatic illness. Anorexia nervosa (AN) is an eating disorder that develops primarily in adolescence and is characterized in part by dangerous food restriction, heightened visceral sensitivity, and altered interoception. Neurobiological models of interoceptive awareness characterize a successive integration of information within the insula, starting with a primary

representation of interoceptive state in the posterior insula and progressively forming a complex unified representation of the self in the anterior insula. We sought to examine differences in developmental trajectories of anterior and posterior insula gray matter volume in female adolescents with AN (N = 22, M_{age} = 17.15) and age matched healthy controls (N = 23, M_{age} = 17.14). Anatomical scans were performed using a FSPGR BRAVO sequence acquired in the axial plane, with an image matrix of 256 x 256 and 1-mm isotropic voxels. Reconstructed images were manually segmented using ITK-SNAP software, separately demarcating anterior and posterior insula (bounded by the central insular sulcus) within each hemisphere. Following segmentation, volumes were normalized relative to the total intracranial volume for each subject. Changes in relative volume were assessed using an analysis of covariance including clinical group, linear age, and nonlinear age, along with relevant interaction terms, as regressors in the model. The analysis revealed significant linear and nonlinear effects of age for both the left and right anterior insula, showing an asymptotic reduction in relative volume independent of clinical status. Additionally, significant interactions between clinical group and linear as well as nonlinear age were evident in the right posterior insula, indicating a relative increase in volume during mid-adolescence for clinical compared to control subjects. These results support neurobiological models implicating insular dysfunction in AN as well as models emphasizing mid-adolescence as a key inflection point for structural changes in social and affective brain function that may confer vulnerability to psychiatric illness. Furthermore, the findings highlight a potential substrate for alterations in visceral sensitivity and interoceptive processing commonly associated with AN.

Title: ATP and its receptor P2X2 and P2X3 in oral cancer induced pain

Authors: *Y. YE[1], K. ONO[2], D. BERNABE[2], C. VIET[2], J. DOLAN[2], A. FORD[3], B. SCHMIDT[2];

Abstract: Extracellular ATP is an endogenous fast-acting neurotransmitter and plays a key role in pain signaling. ATP signals pain through peripheral P2X2 and P2X3 receptors in animal models of inflammatory and neuropathic pain. The role of ATP and its receptor P2X2 and P2X3 in oral cancer induced pain is less clear. In the present study, we used a translational approach studying both human and animal models of oral cancer in parallel. ATP concentration was measured using HPLC in human oral squamous cell (SCC) carcinoma tissues. Pain levels were measured using a validated oral cancer pain questionnaire. A strong positive correlation of ATP concentration in the tumor and levels of pain in oral cancer patients were found. We also found that human SCC is densely innervated by sensory fibers expressing both P2X2 and P2X3 receptors. Our calcium imaging and patch clamping data showed that SCC releases ATP that can directly activate trigeminal ganglion (TG) neurons expressing P2X2 and P2X3 receptors. Using three different animal models of SCC, we demonstrated that selective P2X3 and P2X2/3 antagonists significantly reduced SCC-induced pain as measured by an electronic von Frey and a gnawing assay. Co-culture with SCC increased expression of both P2X2 and P2X3 receptors in TG neurons, which is modulated by nerve growth factor (NGF) in the SCC microenvironment. Our results demonstrate that ATP and its receptors P2X2 and P2X3 play significant roles in oral cancer pain both in human and animal models.

Title: Baseline and change resting-state functional correlates of rTMS of the DMPFC for medically refractory anorexia and bulimia nervosa

Authors: *K. DUNLOP[1], T. SALOMONS[3], N. BAKKER[4], J. GERACI[3], P. GIACCOBE[3,5], M. OLMSTED[2], P. COLTON[2], B. WOODSIDE[2], J. DOWNAR[2,5,3];

[2]Dept. of Psychiatry, [1]Univ. of Toronto, Toronto, ON, Canada; [3]Dept. of Psychiatry, Univ. Hlth. Network, Toronto, ON, Canada; [4]Inst. of Med. Science, Univ. of Toronto, Toronto, ON, Canada; [5]MRI-Guided rTMS Clinic, Toronto Western Hosp., Toronto, ON, Canada

Abstract: Transcranial magnetic stimulation (rTMS) has been recently suggested as a potential treatment for anorexia and bulimia nervosa. Previous research has shown modest efficacy with rTMS for eating disorders using the conventional dorsolateral prefrontal cortex target. However, recent neuroimaging research suggests that the dorsomedial prefrontal cortex (DMPFC) is a key region for impulse control and behavior regulation, including bingeing and purging behaviour. Thus, the DMPFC may be a potential rTMS target for the treatment of eating disorders. 20 patients with treatment refractory anorexia and bulimia nervosa underwent 20 sessions of open-label, add-on rTMS to the DMPFC (10 Hz bilateral stimulation, 120% resting motor threshold). Clinical measures, structural and resting-state scans were obtained before and after treatment. Analysis was performed in FSL. Data was first pre-processed (motion corrected, spatially smoothed, regression of global, white matter and cerebrospinal signal, bandpass filtered). Following pre-processing seed-based resting state analysis was performed for *a priori* regions-of-interest (bilateral ventral striatum [BVS] and subgenual cortex [sgACC]) and a region in proximity to the area stimulated (DMPFC). Purges/week change (baseline-week 4) categorized subjects into a responder (improvement over 50%) or a non-responder (improvement under 50%). This was used as a regressor for the following group-level analysis: 1) baseline connectivity, and 2) connectivity change. Clinical results showed that purging from baseline to week 4 improved from 25.3±38.8 episodes/week to 17.3±19.2 episodes/week. Baseline DMPFC connectivity was not significantly correlated to response. However, for the BVS seed, high pre-treatment functional connectivity to the precuneus and posterior cingulate cortex (PCC), and for the sgACC seed, high pre-treatment functional connectivity to the precuneus and PCC and low functional connectivity to the right hippocampus and amygdala and midbrain Raphé nuclei, were significantly correlated to clinical response. sgACC connectivity change was not significantly correlated to treatment response. It was found that decreased BVS connectivity to the precuneus and PCC and decreased DMPFC connectivity to the frontopolar cortex were significantly correlated to clinical response. In general, this preliminary study showed altered connectivity in midbrain serotonergic structures and corticostriatal and corticocortical pathways previously implicated in emotion regulation and in the pathophysiology of disordered eating behaviour. A randomized control trial as a next step may be warranted.

Abstract: Transcranial Magnetic Stimulation (rTMS) is a technique that allows non invasive electrical stimulation of the cortex with few side effects. It has been proposed an antidepressant effect when rTMS is delivered over prefrontal dosrolateral cortex (DLPFC) ≥ 5Hz. Quantitative EEG studies have shown increases in alpha and theta power bands as well as frontal interhemispheric asymmetries in most recordings from depressed patients. rTMS over left DLPFC at 5Hz involve a safer and more tolerable procedure however its neurophysiological correlates has not been explored using EEG source analysis. The aim of this research was to study changes in EEG sources using VARETA method in a group of patients with major depressive disorder (MDD) treated with 5 Hz rTMS over left DLPFC as single or combined treatment with escitalopram. Methods: 18 patients with DSM-IV MDD diagnosis without treatment for the current episode were included. Subjects were randomly assigned to one of two groups: A) rTMS + escitalopram 10mg, n=9; B) rTMS + placebo, n=9. Subjects received 15 sessions of rTMS on a daily basis. In order to compare changes in EEG sources two recordings were obtained, prior and after treatment. HDRS, BDI and HARD were used for clinical assessments. Results: All patients of group A and 8 patients of group B showed response to treatment (considered as a reduction of 50% in HDRS score). An increase in absolute power at 9.37 Hz and 10.17 Hz in temporal and postcentral gyrus on the left hemisphere was found in group B, on the contrary absolute power those frequencies were decreased in the same regions for group A. In addition an increased power in beta band frequencies were observed in both

hemispheres for group A. Conclusion: Increases in alpha band could be the hallmark of the 5 Hz rTMS, but it could be reduced by escitalopram. Besides, increases observed in beta band for group A could be related to escitalopram effect.

Title: Study of association between brain-derived neurotrophic fator polymorphism (BDNF Val66Met) and suicide risk in a population-based study

Authors: *G. GHISLENI[1], F. P. MOREIRA[1], F. N. KAUFMANN[1], J. D. FABIÃO[1], E. SCHUCH[1], R. A. SILVA[1], D. CRISPIM[2], D. R. LARA[3], M. P. KASTER[1];

Abstract: Brain-derived neurotrophic fator (BDNF) is a member of the neurotrophin growth factor family and mediates neural plasticity, mood, different behaviors, and stress response. A functional BDNF polymorphism (Val66Met) was associated with depression and suicidal behavior. The goal of the present study was evaluate the association between BDNF Val66Met variants and suicide risk in a population-based study. This study was carried out with 482 subjects of the South of Brazil evaluated with a structured diagnostic interview - Mini-International Neuropsychiatry Interview (M.I.N.I; Sheehan et al., 1998). The BDNF Val66Met polymorphism was genotyped by qPCR from 386 control and 96 subjects with suicide risk and the groups were subdivided according to gender. The Val66Met genotypes were in agreement with those predicted by the HWE. All participants gave written informed consent and the ethic committee approved the study. The studied population have mean age of 26.33±5.1 years, 62.4% are women and 80.2% are caucasian. Between subjects with suicide risk 83.2% (n=79) have

major depression and 43.2% (n=41) bipolar disorder (p=0.001). Frequency of BDNF Val66Met genotypes was different between gender [24.9% (n=75) Val/Met-Met/Met in women vs 34.8% (n=63) Val/Met-Met/Met in men; p=0.026], but did not differ for age (26.28±5.1 Val/Val vs 26.43±5.1 Val/Met-Met/Met; p=0.767) and ethnicity [30.2% (n=117) Val/Met-Met/Met in caucasian vs 22.3% (n=21) Val/Met-Met/Met in non-caucasian; p=0.169]. All included suicide risk subjects and the control groups were not different for Val66Met genotypes frequency [32.3% (n=31) Val/Met- Met/Met vs 27.7% (n=107) Val/Met-Met/Met; respectively, p=0.447). The BDNF Val66Met also not differ between suicide risk subjects and the control groups for the women [30.0% (n=21) Val/Met / Met/Met vs 23.4% (n=54) Val/Met, Met/Met; respectively, p=0.335], and male groups [38.5% (n=10) Val/Met / Met/Met vs 34.2% (n=53) Val/Met, Met/Met; respectively, p=0.841]. The combined Met/Met and Met/Val was not significantly associated with suicide risk in the population studied, suggesting that BDNF Val66Met is not predictor of risk for suicide attempt in subjects with mood disorder.

Title: Evaluation of CYP2C19 genotype influence on dose-response to treatment by escitalopram

Authors: *P. C. GHEDINI, R. B. BRITO, K. S. A. SILVEIRA;
Federal Univ. of Goiás, Goiânia, Brazil

Abstract: The CYP2C19 gene presents variation sites that may affect the pharmacokinetics of several drugs of clinical importance, including antidepressant medications as escitalopram. In this study, we investigate the impact of CYP2C19 genotype on escitalopram treatment in patients with remission of depressive symptoms taking this antidepressant at oral doses of 10, 15 or 20 mg/day and with an average use of 2.5 years. DNA was extracted from blood samples obtained

from 22 patients (6 males and 16 females, aged 22-66 years) and CYP2C19*2 and *3 mutations were evaluated by PCR-RFLP. All experiments were approved by the local Ethics in Research Committee (Protocol CEP/UFG 204/2009). Two genotypes were found in the present samples, including 16 subjects (72.7%) with no mutated alleles (*1/*1) and 6 (27.3 %) with one mutated allele (*1/*2). No sample was found carrying two CYP2C19 mutated alleles (*2/*2) and *3 allele was not found in the present series. The dose of 15 mg/day escitalopram was the most frequent in patients carriers of loss-of-function *2 allele (4; 66.8%), whereas the doses of 10 and 20 mg/day had the same distribution (1; 16.6%). These results were not different when compared to non-carriers of *2: 62.6% (10), 18.7% (3) and 18.7% (3) for doses of 15, 10 and 20 mg/day, respectively. The influence of sex and age was not observed. Despite several limitations including the lack of serum drug levels and the sample size of patients, this preliminary study suggested that there isn't influence of CYP2C19*2 on dose-response to chronic treatment by escitalopram.

Title: Altered functional connectivity of subgenual anterior cingulate cortex during negative emotion processing in adolescents with depression

Authors: *T. C. HO[1], G. YANG[2], J. WU[1], G. A. FONZO[3], C. G. CONNOLLY[1], M. CHAN[2], N. HOANG[1], A. N. SIMMONS[2,4], T. YANG[1];
[1]Psychiatry, Univ. of California, San Francisco, San Francisco, CA; [2]Psychiatry, UCSD, La Jolla, CA; [3]Psychiatry, Stanford Univ., Stanford, CA; [4]Veterans Affairs San Diego Hlth. Care Syst., San Diego, CA

Abstract: Major depressive disorder (MDD) typically begins during adolescence and confers a high risk of recurrence in adulthood. Recent evidence suggests that adult MDD is partially characterized by dramatic alterations in the functional connectivity of brain regions involved in emotion processing (Stuhrmann et al., 2011). Thus, examining the functional connectivity of these areas in adolescent MDD could elucidate the etiology and progression of this disorder within the context of brain changes that occur during this sensitive period of development. The

subgenual anterior cingulate cortex (sgACC) and its connected circuitry are heavily implicated in emotion function and as such, may be more susceptible to changes caused by MDD during adolescence (Cullen et al., 2009; Davey et al., 2012). However, few studies have investigated functional connectivity of the sgACC in depressed youth during the processing of emotionally negative stimuli. Using functional magnetic resonance imaging (fMRI), we scanned 45 medication-naïve adolescents (ages 13-17 yrs): 19 MDD and 26 healthy controls (HCL). Depression severity was measured with the Beck Depression Inventory (BDI) and the Children's Depression Inventory (CDI). Subjects performed a gender recognition task of faces exhibiting varying degrees of fear (strong, moderate, and weak) during scanning. We defined seeds in bilateral sgACC and assessed functional connectivity using the psychophysiological interaction method (Friston et al., 1997). First, we found significantly increased functional connectivity between the sgACC and the insula during viewing of strong versus weak fear stimuli in the MDD relative to HCL group. Second, we found decreased functional connectivity between the sgACC and dorsal frontal regions and between the sgACC and dorsal ACC during viewing of strong versus weak fear stimuli in the MDD relative to HCL group. Importantly, the strength of connectivity between the sgACC and dorsal ACC in our MDD group correlated positively with BDI and CDI scores. Our observation of elevated connectivity between the sgACC and insula may be due to increased activation in these structures resulting from enhanced processing of negative stimuli. Likewise, our finding of diminished connectivity between sgACC and cingulate and frontal areas may also reflect decreased regulation of cingulate activation in response to negative emotional stimuli. Similar results have also been reported in adults with depression (Stuhrmann et al., 2011). Our study therefore offers preliminary evidence that aberrant connectivity observed in adolescent-onset depression may affect connectivity patterns seen in adult depression.

Title: Neuroimaging predictors of treatment response to intermittent theta-burst repetitive transcranial magnetic stimulation of the dorsomedial prefrontal cortex in refractory depression

Authors: *N. BAKKER, IV[1], J. DOWNAR[5,2,3], P. GIACOBBE[5,2], T. SALOMONS[5], J. GERACI[5], K. DUNLOP[4], D. BLUMBERGER[2,6], Z. J. DASKALAKIS[2,3,6], S. KENNEDY[2,5,3], A. FLINT[2,5,3];

Abstract: The conventional target of repetitive transcranial magnetic stimulation (rTMS) for refractory major depressive disorder (MDD) has been the dorsolateral prefrontal cortex (DLPFC), but convergent evidence from lesion, stimulation, and neuroimaging studies suggests that the dorsomedial prefrontal cortex (DMPFC) might serve a more central function in emotion regulation. We recently targeted the DMPFC with 10 Hz rTMS in an open-label case series of 47 patients with MDD and found that it was safe, tolerable, and effective, with 51% of patients responding and 43% of patients achieving remission. We also observed a bimodal response pattern, such that patients either experienced minimal or marked improvement. Before treatment, non-responders showed disrupted hedonic function and abnormal connectivity in reward circuity, whereas responders showed preserved hedonic function and normal connectivity in reward circuitry. Although promising, the major limitation with 10 Hz rTMS is the long duration of each treatment session, requiring 40 minutes per day over 20-30 sessions. Drawing on recent studies suggesting that intermittent theta-burst (iTBS) protocols can achieve stronger effects in less time, we targeted the DMPFC with iTBS for 7 minutes per day over 20-30 sessions in an open-label case series of 47 patients with MDD. Despite the significant reduction in treatment time, we found that iTBS of the DMPFC was just as effective as 10 Hz rTMS, with 49% of patients responding and 43% of patients achieving remission. We also collected pre-treatment resting state functional neuroimaging data, which were analyzed using graph theoretical measures and will be discussed in relation to our previous findings linking non-response to anhedonia and abnormal reward circuitry. These results emphasize the utility of iTBS rTMS of the dmPFC for treating refractory MDD and suggest that hedonic functioning and reward circuitry could help predict treatment response.

Title: A common snp variant in FKBP5 is associated with global reductions in levels of mediodorsal thalamic miRNAs in controls and schizophrenia, but not depression

Authors: *K. A. YOUNG, E. S. CARTER, D. PAPPALARDO CARTER;
Psychiatry & Behavioral Sci., Texas A&M HSC / Central Texas VA, Temple, TX

Abstract: FKBP5 encodes an immunophilin which plays a role in immunoregulation, protein folding/ trafficking, calcineurin inhibition, progesterone receptor and heat shock protein complexes and glucocorticoid receptor (GR) regulation. Genetic alterations in FKBP5, including the common SNP variant rs1360780, have been repeatedly implicated as a risk factor for mood disorders. We have previously found genetic influences on structural alterations in the mediodorsal thalamic nucleus in major depression (MDD) and schizophrenia (SKZ), which is of interest because this nucleus extends robust projections to the frontal cortex mediating aspects of frontal cortex dysfunction in these two conditions. MicroRNAs (MiRNAs or miRs) are small non-coding RNAs which modify gene expression and other processes, usually by regulating protein translation. We investigated the possibility that the intronic SNP rs1360780 influences MDD susceptibility though alterations in miRs by assaying levels of 750 human miRs in the mediodorsal thalamic nucleus with RT-PCR panels (Exiqon). In the cohort as a whole, we observed that the common risk genotype for FKBP5 (CT) was associated with a global average 4-fold reduction in 737 out of 750 miRs. 298 of the reductions were significant at a $p<0.05$ level, while no MiRs were significantly elevated. Randomly chosen miRs (hsu-miR-584, -7693-p, -877*, -93, -933, -937) with p values approaching, or less than $p<0.01$ were studied in more detail. The four-fold reduction with CT genotype remained significant after co-varying for diagnosis, age, gender, PMI and pH, and in the two psychiatric subgroups, suicide was not

significantly associated with miR levels. Although we did not observe a main effect of diagnosis on miR levels, we did observe an interaction, with miR reductions associated with the CT genotype being accentuated in controls and SKZ to an average 7-fold reduction, contrasting with a loss of the CT genotype effect in the MDD group (average fold change = - 0.15). Although the mechanisms responsible for these observations remain obscure, it is known that glucocorticoids can suppress expression of key miR processing enzymes including Drosha, Dicer, and DGCR8/Pasha. By sensitizing GR activity or altering its nuclear translocation, the FKBP5 rs1360780 "T" allele may contribute to reductions in miR processing activity, instigating a global down-regulation of the miRnome. Cells with a globally repressed microRNA regulation system may be at higher risk for malfunction under stress, contributing to a neurobiological basis for susceptibility to a variety of stress related disorders such as MDD.

Title: Neural predictors of antidepressant treatment response to Quetiapine XR and Citalopram in Major Depressive Disorder

Authors: *A. BURGESS[1], R. WHITE[1], F. CORTESE[2], B. GOODYEAR[2], A. PANICKER[1], A. KARNES[1], K. ROY[1], V. DIWADKAR[1], R. RAMMASUBBU[2];
[1]Psychiatry and Behavioral Neurosci., Wayne State Univ. Sch. of Med., Detroit, MI; [2]Univ. of Calgary, Calgary, AB, Canada

Abstract: Background: Clinical response to antidepressant treatment is varied and unpredictable in patients with major depressive disorder (MDD). Imaging studies have shown general neural predictors of clinical improvement to antidepressants (Pizzagalli 2011). However, identifying differential predictors of clinical response to antidepressants with different pharamacological profiles may help match patients with appropriate anti-depressants early in treatment. Here we investigated general and specific neural predictors of antidepressant treatment response to citalopram and quetiapine XR treatment in MDD.
Methods: During fMRI (3T), 46 subjects with MDD participated in a picture-matching task (Hariri et al., 2003) during which subjects' matched pairs of faces (or geometric objects) among triads of stimuli. The event-related design was analyzed in SPM8 using standard methods. Pre-

trial fMRI responses were compared (based on end outcome; 8-week) between clinically improved and non-improved groups. 2nd level random effects analyses of fMRI data assessed activity-related differences for both positive and negative valence classes. Analyses were thresholded to a depression and treatment recovery neural circuit consisting of the amygdala, dorsal ACC, subgenual ACC, precuneus, orbito-frontal, and dorsolateral frontal cortex.
Results: Responders to antidepressant treatment showed increased pre-treatment activation in frontolimbic regions including the dorsal nexus, dorsal prefrontal cortex, ACC, orbitofrontal cortex and amygdala (Figure 1).
Conclusions: These findings confirm that pre-treatment anterior cingulate activity to negative emotions may represent generic predictor of clinical improvement to antidepressants. Future studies should examine whether functional interactions of ACC with other regions implicated in emotional regulation or depression differentially predict antidepressant response.

Title: The Additive Impact of Clinical Depression on white matter abnormalities in veterans with Co-morbid PTSD &Traumatic Brain Injury: A diffusion tensor imaging study

Authors: L. ISAAC[1], K. MAIN[1], S. SOMAN[1], J. KONG[1], I. GOTLIB[2], A. FURST[1], J. ASHFORD[1], M. ADAMSON[1], *P. J. BAYLEY[3,1];
[1]War Related Illness and Injury Study Ctr., VA Palo Alto Heatlh Care Syst., Palo Alto, CA; [2]Stanford Univ., Stanford, CA; [3]Stanford/Va Aging Clin. Res. Ctr., Palo Alto, CA

Abstract: A significant proportion of military personnel deployed in support of Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) have been exposed to war-zone events that are potentially associated with traumatic brain injury (TBI), major depressive disorder (MDD) and posttraumatic stress disorder (PTSD). The co-occurrence of TBI, PTSD,

and MDD in returning veterans and the symptom overlap among the three disorders has fueled both research and clinical interest in elucidating the unique and shared effects of such injuries. The purpose of this study was to test the hypothesis that white matter abnormalities are present in association fibers of the uncinate fasciculus (UF), a key fronto-temporal tract involved in mood regulation, and cingulum bundle (CB), a tract that connects to the hippocampus and is involved in memory integration to other parts of the brain. Both the UF and CB tracts, considered part of the limbic system, are posited to be involved in emotion processing, attention, and memory, all of which have been implicated in depression. We performed diffusion tensor imaging on 25 patients with a combination of PTSD, TBI and MDD and 20 patients with PTSD and TBI without MDD matched on age (M = 44.65, SD = 12.0), gender distribution (88% male), education (M = 13.96 , SD = 2.28), and deployment duration in years (M = 7.9, SD = 3.5). We measured the impact of clinical depression on white matter integrity by comparing these two patient groups, who were differentiated only with respect to the presence or absence of MDD. A hierarchical logistic regression model comparing fractional anisotropy (FA) values revealed that after controlling for age, the model correctly classified and distinguished 86.2% of patients who had PTSD, TBI and MDD from the patient group with PTSD and TBI alone. However, the model was able to correctly classify only 61.3% of the patients who had only PTSD and TBI. The regression coefficients indicated that both the right CB ($\beta = 21.04$, $p = .05$) and the left UF ($\beta = 32.05$, $p = .045$) were significant predictors of group assignment. Both the left UF and the right CB had significantly lower FA values in the group with MDD. Our findings provide new evidence of microstructural changes in white matter in Veterans with clinical depression. These results complement those obtained in previous work on depression and support the hypothesis that the disruption of cortical-subcortical circuit integrity is involved in the etiology of MDD. Thus, a detailed examination of the tracts that connect these regions has implications for the management, treatment, and pathophysiology of these commonly observed co-morbidities in the veteran population.

Title: Cerebrospinal fluid glutamate concentration correlates with impulsive aggression in human subjects

Authors: E. F. COCCARO, R. LEE, *P. VEZINA;
Dept Psychiatry and Behavioral Neurosci., The Univ. of Chicago, Chicago, IL

Abstract: Neurochemical studies have pointed to a modulatory role in human aggression for various central neurotransmitters. Some (e.g., serotonin) appear to play an inhibitory role, while others appear to play a facilitator role. While recent animal studies of glutaminergic activity suggest a facilitator role for central glutamate in the modulation of aggression, no human studies of central glutaminergic indices have yet been reported regarding aggression. Basal lumbar cerebrospinal fluid (CSF) was obtained from 38 physically healthy subjects with DSM-IV Personality Disorder (PD: n = 28) and from Healthy Volunteers (HV: n = 10) and assayed for glutamate and other neurotransmitters in CSF and correlated with measures of aggression and impulsivity. CSF glutamate levels did not differ between the PD and HV subjects but did directly correlate with composite measures of both aggression and impulsivity and a composite measure of impulsive aggression in both groups. These data suggest a positive relationship between CSF glutamate levels and measures of impulsive aggression in human subjects. Thus, glutamate function may contribute to the complex central neuromodulation of impulsive aggression in human subjects.

Title: Discharge rates of neurons in the posterior hypothalamus region in Sotos syndrome

Authors: *W. D. HUTCHISON[1], R. MICIELI[2], N. TRUJILLO[3], A. LOPEZ RIOS[4];
[1]Div. Neurosurg., Toronto Western Hosp., Toronto, ON, Canada; [2]Physiol., Univ. of Toronto, Toronto, ON, Canada; [3]Neurosci., Univ. of Antioquia, Medellin, Colombia; [4]Centros Especializados Rionegro, Hosp. San Vicente Fundacion, Medellin, Colombia

Abstract: Deep brain stimulation (DBS) of the posterior hypothalamus (PH) has been reported to be effective for aggressive behaviour in a number of isolated case studies. Sotos syndrome is rare genetic (NSD1- nuclear set domain) disorder leading to cerebral gigantism and neuropsychiatric problems in children, including aggression. Single unit neuronal recordings in the human PH have been reported in cluster headache (Sani et al. Neurosurg 64: 161, 2009), but not for Sotos syndrome. We report on the properties of ongoing neuronal discharge in bilateral trajectories targeting PH in a young female with Sotos syndrome. Initial target coordinates, determined by magnetic resonance imaging stereotactic localization, were 2 mm lateral, 3 mm posterior, and 5 mm inferior to the midpoint of the anterior commissure- posterior commissure line. Two microelectrodes were driven down the central and lateral guide tubes of the Guideline 4000 system (Frederick Haer) starting at 15 mm above the tentative target in PH under local anesthetic only. Single units were discriminated off-line by template matching using Spike2 software (CED). Average firing rates and oscillatory activity were compared for three regions, ventral thalamus (n=12 units), PH region (n=15) and red nucleus (n = 4). The ventral thalamus appeared to have two populations of neurons, one with a high firing rate (16.5 +/- 7.0 Hz n=6) and one with a low firing rate (5.1 +/- 3.1 Hz, n=6). Most of the PH region units had a slow, irregular discharge (5.7 +/- 3.4 Hz, n=10) but some units also had a higher rate (19.3 +/- 5.8 Hz, n=5). The mean discharge rate of PH units was not significantly different overall than that of ventral thalamus. Red nucleus neurons had higher firing rates (25.9 +/- 9.7 Hz, n=4) and regular firing with periods of oscillatory activity in the beta range (15 - 20 Hz). Oscillatory activity was not evident in the PH or ventral thalamus. Early observation indicated that the patient's aggressive behaviour improved with DBS. The findings are similar to the previous published report for cluster headache and help in localization of the proper target in PH for aggressive behaviour.

Title: Dysbalanced intrinsic connectivity of central executive and emotional salience network in borderline personality disorder

Authors: *A. DOLL[1,6], C. SORG[2], C. MENG[1,6], A. WOELLER[3], V. RIEDL[4], A. WOHLSCHLAEGER[5,6];
[1]Neuroradiology, [2]Neuroradiology, Psychiatry, [3]Psychiatry, [4]Neuroradiology, Nuclear Medicine, Neurol., [5]Neuroradiology, Neurol., TUM-NIC Neuroimaging Center, Technische Univ. München, Munich, Germany; [6]Grad. Sch. of Systemic Neurosciences, Ludwig-Maximilians-Universität, München, Germany

Abstract: Borderline personality disorder (BPD) is characterized by "stable instability" of emotions and impulsivity and their regulation. This emotional instability corresponds with a neurocognitive triple network model of psychopathology that suggests that an aberrant relationship between emotional saliency and cognitive control relies on an aberrant integration across intrinsic connectivity networks (ICN) including the salience, default mode, and central executive network (SN, DMN, CEN). The objective of the current study was to analyze whether and how such triple network intrinsic interactions were changed in patients with BPD.
We acquired resting-state functional magnetic resonance imaging (rs-fMRI) data from 16 patients with BPD and 16 matched healthy controls (HC). High-model order independent component analysis (ICA) was used to extract spatiotemporal patterns of ongoing, coherent blood-oxygen-level-dependent signal fluctuations from rs-fMRI data. Inter-ICN time course correlation (inter-network functional connectivity iFC) between ICNs overlapping with canonical SN, DMN, CEN was the main outcome measure of the study.
While patients' iFC of the CEN, critically involved in cognitive control processes, was consistently decreased, only iFC of the SN, associated with emotions, was increased. In particular, a balance index reflecting the relationship of CEN-and SN-iFC across all networks was strongly shifted from CEN to SN connectivity in patients.
Results provide evidence for aberrant triple network iFC in BPD. Our data suggest a shift of iFC

from cognitive control to emotion related brain networks in BPD possibly reflecting the persistent instability of emotion regulation in patients.

Title: Association between antidepressant treatment response and EEG alpha: current source density (CSD) spectral measures at rest and time-frequency (TF) measures during a novelty oddball

Authors: *C. E. TENKE, J. KAYSER, J. E. ALVARENGA, K. ABRAHAM, D. M. ALSCHULER, G. E. BRUDER;
Div. Cognitive Neurosci., NYS Psychiatric Inst., New York, NY

Abstract: EEG alpha rhythm has been used as a neurophysiological measure of activation, ranging from relaxation at rest to task-related local cortical synchronization or desynchronization. Although the topographic capacity of high density EEG is limited by volume conduction, CSD transformation provides reference-free measures that represent the neuronal generator pattern underlying alpha. CSD-based frequency principal components analysis (CSD-fPCA) of resting EEG has identified posterior, condition-dependent (eyes open/closed) alpha as a predictor of antidepressant treatment response (Tenke et al 2011). However, alpha also varies during the performance of behavioral tasks, and these changes may be quantified as event-related spectral perturbations (ERSP). The present study combined resting- and task-related (novelty oddball) CSD alpha measures obtained from a 67-channel montage in depressed patients prior to treatment with a serotonergic antidepressant (n = 77) or bupropion (n = 23). Oddball EEG was epoched (-200 to 800 ms) for each condition (target, nontarget, novel), CSD-transformed, and submitted to FFT-based TF analysis to yield ERSP and corresponding baseline spectra. The TF dataset was simplified and quantified by unrestricted PCA (CSD-tfPCA), yielding a prominent, unambiguous factor quantifying alpha desynchronization (ERD), characterized by loadings

peaking at 490 ms (350-700 ms) and 10 Hz (7-12.5 Hz) and scores with a posterior topography for novels and targets, but not nontargets. Resting and task-related baseline EEG alpha were quantified by CSD-fPCA, and submitted to repeated measures ANOVAs with treatment (serotonergic, bupropion), response (responder, nonresponder), and gender as between-factors. The Beck Depression Inventory (BDI) measure of pretreatment depression was used as a covariate because BDI was correlated with condition-dependent alpha at rest ($r = .253$, $p = .01$) and post-stimulus ERD ($r = .212$, $p = .03$). For alpha at rest, we replicated the finding of greater condition-dependent alpha in responders than nonresponders for both treatments. In contrast, task-related alpha (prestimulus baseline or ERD) showed no association with treatment response. However, the overall amplitude of task-related alpha showed a significant treatment by response interaction, where bupropion responders showed less task-related alpha than nonresponders, but this difference was not seen for serotonergic treatment. In conclusion, alpha oscillations at rest and during a novelty oddball task are related to depression and antidepressant treatment response, suggesting distinct processes that modulate default mode activity.

Title: A transporter-independent site for SSRI action

Authors: *J. SCHAPPI[1], A. CZYSZ[2], M. RASENICK[3];
[1]Physiol. & Biophysics, [2]Neurosci. Program, [3]Physiol. & Biophysics, Neurosci. Program, Psychiatry, Jesse Brown VAMC, Univ. of Illinois At Chicago, Chicago, IL

Abstract: Chronic treatment of cells or animals with varied antidepressants promotes the redistribution of Galphas from lipid rafts into non-raft membrane fractions. The net result of this redistribution is increased Galphas coupling with transmembrane adenylyl cyclase, and increased cAMP production. These changes are demonstrated via immunoblot, functional assays, and imaging studies. This phenomenon is seen in vivo as well as in cell lines such as C6 glioma and

PC12 pheochromocytoma. These cell lines, however, lack serotonin transporter (SERT), a high-affinity target of selective serotonin reuptake inhibitor-class antidepressants (SSRIs), suggesting that response to monoamine centered antidepressants entails more than inhibition of neurotransmitter reuptake transporters or inhibition of monoamine breakdown. Furthermore, Galphas localization and cAMP production in kidney epithelial cells like COS7 and HEK293 were unchanged by antidepressant treatment. Similarly, membranes from liver and kidney of rats treated chronically with antidepressant did not differ from control animals. One trait shared by cell lines studied, both antidepressant responsive and unresponsive, is a lack of SERT, a binding site of and putative therapeutic target for SSRI antidepressants. Data from this study demonstrate the following: Transgenic expression of SERT in both antidepressant responsive and unresponsive cells does not result in altered antidepressant response compared to wild type. Therapeutically inactive stereoisomer R-citalopram does not cause the characteristic changes in G-protein and cAMP signaling in responsive cell types as seen with S-citalopram. These findings suggest the existence of another yet-unidentified specific target and mediator of SSRI antidepressant action separate from SERT and potential target of new antidepressant drugs.

Title: Pre-treatment subcortical volumes and antidepressant response to ketamine: A predictive analysis

Authors: *C. M. SINCLAIR, A. C. NUGENT, D. A. LUCKENBAUGH, C. A. ZARATE; NIMH / ETPB, NIH, Bethesda, MD

Abstract: Research suggests that dysfunction of the limbic-cortical-striatial-pallidal-thalamic circuit (LCSPT) is connected to the pathophysiology of major depressive disorder (MDD). Previous studies have shown that MDD is associated with subcortical volumetric reductions in the hippocampus (Lorenzetti et al., 2009; Amico et al., 2011), thalamus (Vasic et al., 2008; Kim et al., 2008), caudate (Koolschijn et al., 2009; Kim et al., 2008; Parashos et al., 1998), putamen (Koolschijn et al., 2009; Parashos et al., 1998), and amygdala (Hamilton et al., 2007) as compared to healthy controls. This exploratory study investigated whether the volumes of the thalamus, caudate, putamen, hippocampus, and/or pallidum of patients with MDD correlate with antidepressant response to ketamine, a rapid-acting experimental treatment for depression. MDD subjects (N=31) received a baseline T1 weighted MRI on a 3T scanner, from which all of the above-mentioned subcortical volumes were extracted using FIRST (FMRIB's Integrated Registration and Segmentation Tool, University of Oxford, UK). Brain volumes were then correlated with antidepressant response to ketamine, measured as the percent change in Hamilton Depression scores from baseline to 230 minutes after an intravenous ketamine infusion (0.5 mg/kg over 40 minutes). Pearson correlations showed that smaller bilateral thalamus and caudate volumes correlated with greater antidepressant response (thalamus: $p = .021$; caudate: $p = .020$). Both key areas in the LCSPT network, the thalamus and caudate may serve as important targets for ketamine's antidepressant mechanism of action; this may likely be through increased neuronal spine growth (Duman and Aghajanian, 2012) in these areas susceptible to stress-induced neuronal atrophy. In addition, this relationship between thalamic and caudate volume and antidepressant response to ketamine may serve as a useful biomarker for identifying individuals with a greater predisposition for responding to ketamine, or similar future antidepressant treatment compounds acting on the glutamatergic system.

Title: Differences in beta band activity correlate with clinical response to rTMS for depression

Authors: *Y. PATHAK[1], O. SALAMI[2], S. BAILLET[4], Z. LI[3], C. R. BUTSON[3];
[1]Marquette Univ., Milwaukee, WI; [2]Psychiatry, [3]Neurol., Med. Col. of Wisconsin, Milwaukee, WI; [4]McConnell Brain Imaging Ctr., McGill Univ., Montreal, QC, Canada

Abstract: Major Depressive Disorder (MDD) is characterized as a leading cause of disability worldwide. Current treatment options, including pharmacological interventions, psychotherapy and electroconvulsive therapy, have shown varied efficacy. Therefore, neuromodulation therapies such as deep brain stimulation (DBS), cortical stimulation and repetitive transcranial stimulation (rTMS) are being investigated. Of these, rTMS is attractive due to its focal and non-invasive nature. The goal of this study is to investigate the functional changes that result from rTMS for the treatment of MDD by integrating multimodal imaging. rTMS was administered to the left dorsolateral prefrontal cortex (L-DLPFC) based on a previously published stimulation protocol (fitzgerald,2009). Depressive symptoms were assessed using the Montgomery-Asberg Depression Rating Scale (MADRS). Imaging data (magnetic resonance imaging (MRI), electroencephalogram (EEG), magnetoenceophalogram (MEG), and diffusion tensor imaging (DTI)) were collected before, during and after treatment to evaluate longitudinal changes. Power spectral density (PSD) analysis and functional connectivity analysis were conducted using this data. Results from the MADRS were used to classify subjects as responders or non-responders. PSD results from the MEG data revealed contrasting differences between one responder and one non-responder. For the responder, there was a marked increase bilaterally in the frontal regions for both mid-point and end-point. However, this increase didn't persist at the 2-month follow up. For the non-responder, increase in activity of the frontal regions is lower during treatment and we observed a decrease in power from baseline at follow up, which corresponded to the worsening severity of depressive symptoms. Our results further suggest that functional and structural imaging can be used to evaluate longitudinal changes in functional connectivity and its correlation to clinical response during rTMS treatment for MDD.

Title: Antidepressant treatment decreases glucocorticoid receptor translocation in neuroepithelial cells from living individuals with major depression and controls

Authors: B. R. WILLIS[1,2], *D. SINCLAIR[1], S. JEFFERSON[1], A. MANCEUR[1], O. BERTON[3], C.-G. HAHN[1], K. BORGMANN-WINTER[1,4];
[1]Neuropsychiatric Signaling Program, Univ. of Pennsylvania, Philadelphia, PA; [2]Bryn Mawr Col., Philadelphia, PA; [3]Univ. of Pennsylvania, Philadelphia, PA; [4]Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Background: In major depressive disorder (MDD), elevated stress hormone levels have been consistently reported. Stress hormone dysregulation may be due to impaired function of the glucocorticoid receptor (GR), a key mediator of cellular stress responses and hypothalamic-pituitary-adrenal (HPA) axis negative feedback. Indeed, translocation of GR to the nucleus, an event central to its function, is significantly decreased in vitro, in neuroepithelial cells derived from MDD patients relative to controls. Antidepressants can normalize HPA axis activity in individuals with MDD, but it is not known whether modulation of GR translocation by antidepressants occurs in the brain, and represents a mechanism underlying the therapeutic effects of antidepressants in MDD. Therefore, we employed cultured neuroepithelial cells from the olfactory epithelium (OE), the only cells of putative neural origin which can be propagated from living human subjects, to investigate GR translocation in response to antidepressant treatment in MDD patients and healthy controls. Methods: OE culture neuroepithelial cells from MDD patients (n=3) and controls (n=4) were treated for 2 hrs, 1 day or 4 days with fluoxetine

(an SSRI), desipramine (an SNRI), or duloxetine (a TCA), each at 1uM or 10uM, and GR translocation quantified using automated fluorescent microscopy (ImageXpress, Molecular Devices). Results: Treatment with fluoxetine, desipramine or duloxetine significantly decreased GR translocation in a treatment duration-dependent manner (ANOVA- fluoxetine: $F(2, 48)=3.1$, $p<0.05$; desipramine: $F(2, 48)=5.1$, $p<0.005$); duloxetine ($F(2, 48)=3.4$, $p<0.05$). Greatest decreases in GR translocation were observed after 10uM treatment with fluoxetine for 4 days (-18.5%), desipramine for 4 days (-14.3%) and duloxetine for 1 day (-23.0%), with minimal effects in all conditions after 2 hr treatment. There were no significant differences in antidepressant effects between MDD and control cells, nor were there significant differences between antidepressants. Conclusions: Antidepressant treatment for an extended duration (≥1 day at 10uM) significantly decreases GR translocation in OE-derived neuroepithelial cells of both MDD patients and healthy controls. Future work to investigate the mechanism through which antidepressants act on GR translocation in OE culture cells may identify new mechanisms of antidepressant action on stress hormone disturbances in MDD.

Abstract: A history of violence and aggressive behavior is often correlated with a reduced ability to learn and adopt adequate behavior, social rules and norms. Psychopathic offenders show both of these externalizing deficits, together with several affective problems such as a lack of remorse, reduced empathy and deficient anticipatory fear. Prior research has shown, that certain aspects of the externalizing characteristics of psychopathy are related to a reduced cortical activity in self-monitoring and error-processing (Hall et al, 2007; von Borries et al.,

2010).
Therefore we hypothesized that self- regulation of brain activity (Slow Cortical Potential (SCP)-Training as described in Birbaumer et al., 1990) could lead to changes in offenders' aggression as well as to altered error processing.
To examine this question, 14 psychopathic offenders with a severe criminal history performed a letter version of the Eriksen Flanker Task and rated different kinds of aggressive behavior before and after SCP- Training.
Significant reductions in physical and reactive aggression and antisocial tendencies, as well as an improved aggression inhibition were detected after SCP- Training. Furthermore a significant increase in Error Related Negativity and Positivity could be observed, after offenders learned to successful regulate their SCPs.
Our results suggest that self-regulation of cortical activity leads to an improved error processing and aggression regulation in psychopathic offenders.

Title: Long-term sertraline treatment increases expression and decreases phosphorylation of glycogen synthase kinase-3b in platelets of patients with late-life major depression

Authors: *H. P. JOAQUIM[1], L. L. TALIB[2], B. S. DINIZ[1], O. V. FORLENZA[2], W. F. GATTAZ[2];
[2]Psychiatry, [1]Psychiatry Intitute HCFMUSP, Lim-27, São Paulo, Brazil

Abstract: Background: Abnormal regulation of glycogen synthase kinase 3-beta (GSK3B) activity has been implicated in the pathophysiology of mood disorders. Many pharmacological agents, including antidepressants, can modulate GSK3B. The long-term treatment with antidepressant may reduce the risk of Alzheimer's disease (AD) in elderly subjects with affective disorders and late-life depression seems to be a risk factor for the development of AD. The neurobiological mechanisms linking these two disorders are unclear, but some proposed mechanisms are: the increased amyloid-beta production during the depressive episode, mediated by the deregulation of the serotoninergic system; the activation of pro-inflammatory cascades, the impairment in the neurotrophic cascades; as well as the abnormal activation of GSK-3B signaling cascade. On the other hand, there is evidence that antidepressants and mood stabilizers, such as lithium, can modulate some of these cascades, in particular GSK3B and neurotrophic cascades.
Objective: Investigate the effect of short- and long-term sertraline treatment on the expression and activity of GSK3B in platelets of patients with late-life major depression.
Methods: 39 no-medicated elderly with major depressive disorder (MDD) were included in this study. The comparison group comprised 18 age-matched, healthy individuals. The expression of total and Ser-9 phosphorylated GSK3B (pGSK3B) was determined in platelets of patients and controls at baseline, and after 3 and 12 months of sertraline treatment by Elisa method.
Results: Depressed patients had higher levels of pGSK3B as compared to controls ($p<0.001$). After 12 months of treatment there was an increase in the expression of total GSK3B ($p=0.05$), in the absence of any significant changes in pGSK3B ($p=0.12$), leading to a reduction in GSK3B ratio ($p=0.001$).
Conclusions: Long-term treatment with sertraline increased GSK3B patient's level to controls values. Our findings suggest that platelet GSK3B ratio may be a useful parameter to establish biochemical changes during antidepressant treatment.

Title: One-time brief vicarious pain is sufficient to enhance fear learning and trigger depression-like behaviors in mice

Authors: *W. ITO, A. MOROZOV;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: (Rationale) Psychological stress is a major trigger of mental disorders, but prevalent rodent models of distress involve physical pain or physical discomfort. Here, we characterized a mouse model of vicarious pain from one-time brief exposure to conspecifics receiving electrical footshocks.
(Experiments and results) Single exposure (duration: 4min) to a distressed cagemate decreased preference to sucrose water measured during the following 12 hours. Moreover, the observers showed enhanced contextual fear and passive avoidance learning, performed 24 hours after the vicarious pain. Despite causing behavioral changes, observing other pain did not increase plasma corticosterone (CORT) more than the control procedure, in which demonstrator did not receive footshocks. A restraint (2hr), however, increased CORT more than the vicarious pain, but did not reduce sucrose preference.
(Discussion) The finding suggests that (1) vicarious pain, even brief, is sufficient to produce lasting changes in mouse brain circuits underlying fear and reward, and (2) the mechanism does not solely involve raise of plasma CORT, as observed in physical stress.

Title: PFC-amygdala circuit in a mouse model of vicarious pain

Authors: *A. Y. MOROZOV, W. ITO;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Psychological trauma, even in the absence of physical distress, is the major cause of mental disorders. Yet, most animal models of distress involve physical pain or discomfort. Here we employed a putative mouse model of psychological trauma elicited by vicarious pain and investigated synaptic transmission between the dorso-medial prefrontal cortex (dmPFC) and the basolateral amygdala, the two brain areas implicated in several mental disorders. To selectively study dmPFC-BLA pathway, channelrhodopsin 2 (ChR2) was expressed in dmPFC neurons using a recombinant adeno-associated viral vector. As a traumatic event, the observer animal was exposed to a cage-mate conspecific (the demonstrator) receiving electrical foot-shocks. On the

next day after the exposure, whole cell recording in amygdala slices from the observer mouse were performed to study synaptic responses evoked in BLA principal neurons upon light stimulation of axonal fibers from dmPFC expressing ChR2. Changes were found in both glutamatergic and GABAergic currents evoked in BLA principal neurons. The AMPA/NMDA ratio was reduced, which coincided with an increase in the amplitude of pharmacologically-isolated NMDA receptor-mediated currents evoked by "minimal" stimulation by a narrow beam of light delivered via a small diaphragm. No changes were found in the AMPA receptor mediated currents. The polysynaptic GABAergic currents had faster rise and decay, which indicates that vicarious pain altered the composition and (or) properties of GABAergic neurons recruited by input from dmPFC. Taken together, our findings suggest that vicarious pain alters communication between dmPFC and amygdala by changing both glutamatergic and GABAergic microcircuits involved in interaction between the two structures.

Title: The role of BDNF-TrkB signaling in dorsal raphe nucleus to mediate antidepressant efficacy

Authors: *M. ADACHI, A. E. AUTRY, L. M. MONTEGGIA;
Univ. Texas Southwestern Med. Ctr., Dallas, TX

Abstract: The molecular basis of antidepressant efficacy for the treatment of major depression is unclear. Several lines of evidence link brain-derived-neurotrophic factor (BDNF) as a target of antidepressant treatment, whereas loss of BDNF has been suggested to underlie certain depressive symptoms. Our laboratory has been investigating the role of BDNF in antidepressant efficacy, as well as depression-like behavior, in mice. We have previously demonstrated that the loss of BDNF in broad forebrain regions attenuates responses to conventional antidepressants in behavioral tests used to predict antidepressant efficacy. More recently, we extended these findings to show that the BDNF-mediated effect on antidepressant efficacy is specific for the dentate gyrus and not other subregions of the hippocampus.

In the present study, we are investigating whether BDNF and its high affinity receptor, TrkB, in dorsal raphe (DR) nucleus contribute to antidepressant efficacy. The DR is a nucleus of serotonergic neurons that provides a large portion of the serotonin innervation to the forebrain, including the dentate gyrus. BDNF and TrkB are highly expressed in the DR and have been suggested to play a role in mediating antidepressant responses but data has not directly examined this possibility. To address this question, we are using a viral mediated gene transfer approach to knockdown BDNF or TrkB selectively in the DR nucleus of adult mice. Adeno-associated virus (AAV) expressing Cre recombinase tagged to GFP (AAV-CreGFP) or AAV-GFP is injected by sterotaxic surgery into the DR of floxed BDNF or floxed TrkB adult mice. The targeted delivery of AAV-CreGFP shows a substantial reduction in Bdnf or TrkB mRNA expression within the DR in comparison to the AAV-GFP injected mice. Mice with localized knockdown of BDNF or TrkB display no obvious abnormalities in overall health and motor function. We are currently assessing emotional behavior as well as responses to conventional antidepressants in these regional specific DR knockdown mice. These data will provide key information on the role of BDNF as well as TrkB in the DR in mediating behavioral responses as well as antidepressant efficacy.

Title: Inhibition of Orexinergic signaling leads to depression-like behaviors in diurnal grass rats

Authors: *S. P. DEATS[1], L. YAN[2];
[1]Psychology, [2]Psychology Dept. & Neurosci. Dept., Michigan State Univ., East Lansing, MI

Abstract: Light has profound effects on humans including mood regulation as exemplified by Seasonal Affective Disorder (SAD) and the beneficial effects of light therapy. However, the underlying neural pathways through which light regulates mood are not well understood. Our previous work has developed the diurnal grass rat, Arvicanthis niloticus, as an animal model of SAD. When housed under a 12:12hr Dim Light:Dark (DimLD) cycle that mimics the lower light intensity of winter, the animals showed increased depression-like behavior compared to the controls housed in bright light during the day (BLD) (Leach et al., 2013). Along with the

behavioral changes, we found that the level of the neuropeptide orexin was reduced in the DimLD animals, suggesting the involvement of orexinergic signaling in light-dependent mood changes. To test this hypothesis further, the present study utilized a selective orexin 1 receptor antagonist (SB-334867). Adult grass rats were kept in the BLD condition for 4 weeks before being exposed to a forced swim test (FST). Based on the immobility time during the FST, paired littermates were assigned into two groups with equivalent average immobility time. On the next day, one group received an injection of SB-334867 (10 mg/kg, i.p.) and the other group received vehicle 4 hrs prior to the FST. The SB-334867 treated group showed significantly longer immobility time compared to the vehicle control group. In addition, a sweet solution preference was reduced in the SB-334867 treated group, but the total amount and daily rhythms of drinking was not affected. The effect of SB-334867 on general locomotor activity and body weight were also assessed, and no significant differences were found between the SB-334867 and vehicle treated groups in those measures. The results suggest that the orexinergic pathway is involved in mood regulation in the diurnal grass rats and that it represents a potential mediator underlying light-dependent changes in mood.

Title: Attenuated orexinergic signaling in a diurnal rodent model of SAD

Authors: *W. ADIDHARMA, L. YAN;
Michigan State Univ., East Lansing, MI

Abstract: Seasonal affective disorder (SAD) is a major depressive disorder recurring in the fall and winter, when there is a reduction of light intensity in our environment. Replenishing the lack of environmental lighting with bright light therapy has been found to be effective in alleviating the depressive symptoms of SAD. Though circadian and monoaminergic systems have been implicated in the etiology of SAD, the underlying neural mechanisms through which light regulates mood are not well understood. To aid in identifying the neural substrates associated

with light-dependent mood changes, we have developed the diurnal grass rat, Arvicanthis niloticus, as an animal model of SAD. By utilizing a 12:12hr Dim Light:Dark (DimLD) paradigm that mimics the lower light intensity in the winter, the animals housed in DimLD showed increased depression-like behaviors compared to animals housed in bright light during the day (BLD) as revealed by forced swim test and sweet solution preference (Leach et al., 2013). Our previous work has found that a selective orexin 1 receptor antagonist (SB-334867) blocks light-induced activation of neurons in the 5-HTergic dorsal raphe (DRN), leading us to suggest the hypothesis that an orexinergic pathway mediates the effects of light on mood (Adidharma et al, 2012). The objective of the present study is to test this hypothesis by investigating the level/intensity of the orexinergic signaling in the grass rats showing depression-like behaviors in DimLD and the controls in BLD. The immunoreactivity of orexin was assessed by immunocytochemistry using standard method. The results revealed a significant reduction in the number of orexin cells in the hypothalamus and in the density of fiber/terminal staining in the DRN of the DimLD group compared to that in the BLD group. The results suggest that he orexinergic pathway plays a role in light-dependent mood fluctuation and in the beneficial effects of light therapy.

Title: Altered pain processing in rats with depressive-like behaviors: A high-resolution EEG/ERP study

Authors: Y.-F. GUO[1,2], Y. XU[1], *J.-Y. WANG[1], F. LUO[1];
[1]Key Lab. of Mental Hlth., Inst. Psychol, Chin Acad Sci., Beijing, China; [2]Grad. Univ. of Chinese Acad. of Sci., Beijing, China

Abstract: Depression and pain disorders are common comorbid conditions and reciprocally affect each other. Significantly reduced acute pain sensitivity has been found in depressed patients and some rodent models of depression. However, mechanisms underlying the impact of depression on pain perception are far from fully understood. This research investigated possible electrophysiological correlates of this disrupted pain experience using the olfactory bulbectomy (OB) model of depression in Sprague-Dawley rats. Electroencephalographic (EEG) activity was continuously recorded through twelve chronically implanted epidural electrodes during the application of brief laser stimuli to the plantar surface of the right hind paw of conscious rats. Behavioral results showed that the likelihood of observing paw withdrawal responses decreased significantly in rats with depressive-like behaviors as compared to controls when the 100 mJ and 140 mJ of laser stimuli were delivered. Time-frequency analysis using wavelet transform and time-domain analysis of EEG signals revealed that the magnitude of laser-induced gamma band oscillations (0-150 ms after stimulus onset, 60-120 Hz) as well as the peak amplitude of evoked potential N70 recorded over the primary somatosensory cortex contralateral to the stimulated side was particularly related to the perceptual variation of identical laser stimuli. Notably, in depressive-like state there was a significant inhibition of this early nociceptive processing subserving the emergence of pain behaviors in rats. In addition, event-related desynchronization of beta rhythm (130-280 ms, 12-30Hz) was markedly disrupted following laser stimulation recorded above the posterior parietal area in OB-treated rats. The present study demonstrates that the modulatory effects of depression on pain perception can be directly observed in the early stages of cortical sensory processing, which may account for the decreased sensitivity to nociceptive stimuli in depressive state. These findings might contribute to a better understanding of the altered responding to the environmental stimuli in depressed individuals.

Title: Augmented antidepressant properties of acute and chronic administration of imipramine in adult female rats treated prenatally with choline supplementation

Authors: *C. EVANGELISTA, N. K. ZIV, M. J. GLENN;
Psychology, Colby Col., Waterville, ME

Abstract: Emerging data point to the neuroprotective capabilities of prenatal supplementation of the essential nutrient choline. Providing pregnant dams with a choline-rich diet during gestation enhances cognition in offspring (Meck & Williams, 2003). In addition, it attenuates the impact of a host of neural insults, such as neurotoxins (Guo-Ross et al., 2002), seizures (Wong-Goodrich et al., 2010), and brain aging (Glenn et al., 2008). A potential mechanism mediating these behavioral and neural benefits is the enhancement in adult neural plasticity, specifically hippocampal neurogenesis and growth factor content (Glenn et al., 2007; 2008). Hippocampal plasticity is widely recognized as integral in the pathological features of psychological disorders such as depression. Our lab recently demonstrated that developmental choline supplementation exerts antidepressant-like effects in adult female rats (Glenn et al., 2012). This effect was similar in magnitude to the antidepressant imipramine (Porsolt et al., 1978). The goals of the present study were to systematically compare the capacity for prenatal choline supplementation to 1) combat despair in the forced swimming test with acute administration of imipramine and 2) reduce anxiety-like behavior, enhance memory, and increase neurogenesis after chronic administration of imipramine. To do this, timed-pregnant Sprague Dawley rat dams were fed diets containing standard (STD) or supplemental (SUP) levels of choline (AIN76A with 1.1 or 5 g/kg choline chloride, respectively) during embryonic days 11-birth. Offspring were cross-fostered and reared in litters of 10 containing males and females from both diet conditions. Female offspring served as subjects, were weaned at postnatal day (PD) 25, and raised to PD 75 for behavioral testing. For forced swim, rats were placed in an inescapable column of water for 10 minutes and then administered two injections, 1 and 23 hrs later, of saline or 7.5, 15, or 30 mg/kg of imipramine. Despair was assessed 24 hrs later in a 5-min retest in the water column. Despair was attenuated by imipramine in STD rats and its effect was significantly greater in SUP rats, particularly at the 30 mg/kg dose. A month later, rats were chronically exposed to the 7.5 and 15 mg/kg doses, or saline, receiving daily injections for 10 days. Compared to STD rats given saline, STD rats given the higher dose of imipramine and SUP rats given saline showed significantly less anxiety-like behavior. Additionally, SUP rats given imipramine displayed the least anxiety. Presently, memory and hippocampal neurogenesis are under investigation to further uncover interactions between choline supplementation and imipramine.

Title: Elucidating novel candidate genes and pathways determining variability in antidepressant response

Authors: *C. LABERMAIER[1], S. H. SCHARF[5], K. V. WAGNER[2], P. WEBER[3], M. UHR[4], M. V. SCHMIDT[2], E. B. BINDER[3], I. SILLABER[6], M. B. MÜLLER[1];
[1]RG Mol. Stressphysiology, [2]RG Neurobio. of Stress, [3]Mol. Genet. of Affective Disorder, [4]Pharmacokinetics and CSF Analysis, Max Planck Inst. of Psychiatry, Munich, Germany; [5]Pharma Res. & Early Development, Discovery Neurosci., F.Hoffmann-La Roche AG, Basel, Switzerland; [6]Phenoquest AG, Munich, Germany

Abstract: Antidepressants are generally effective, but the variability in response and effectiveness is considerably high. Only one-third of patients respond to the first medication prescribed. The identification of genetic factors that might assist in the prediction of an individual's drug response has attracted lot of attention during the last years, but the results from genome-wide association studies for antidepressant response genes have been fairly modest thus far. Moreover, it still remains a mystery why a patient does not respond to the same antidepressant drug in the current depressive episode that was convincingly effective years ago. In this study we were aiming to identify novel candidate genes and molecular pathways, which might be responsible for modulating individual antidepressant response.
Therefore, we designed an animal experimental approach to identify novel candidate genes determining the variability in antidepressant response. We used a genetically homogeneous inbred mouse strain with high innate anxiety (DBA/2J) known to be antidepressant responsive and hypothesized that, when treating a large number of animals chronically with either paroxetine or vehicle, we will be able to identify subgroups of animals which are "good" and "poor" treatment responders according to their performance in the Forced Swim Test. In addition to an overall significant effect of the antidepressant treatment, we detected - despite their genetic homogeneity - a large variability within the paroxetine-treated animals.
Gene expression profiling by means of microarray analysis was then performed with RNA extracted from prefrontal cortex and hippocampus of good and poor treatment responders. We chose these brain regions because brain stimulation and imaging studies in humans have emphasized the role of the prefrontal cortex as a key player in depression and antidepressant response. To enable the identification of genes mediating an early antidepressant response, the same experimental design was applied following 2 weeks of paroxetine treatment corresponding

to the “early response” in the clinical situation. Additional gene expression profiling on RNA extracted from blood samples following 2 weeks of antidepressant treatment might allow the identification of potential peripheral biomarkers associated with early response. Finally, our animal experimental data will be compared and integrated with human genetics data for antidepressant treatment response in patients. We are confident that this translational approach will enable us to identify strong candidates involved in modulation antidepressant response.

Abstract: Major depressive disorder (MDD) is considered to be the second leading cause of disability world-wide, accounting for more lost productivity than any other psychiatric disorder. This is partially attributed to the cognitive decline that accompanies depression, characterized by persistent impairments related to attention, working and episodic memory and executive functions. The debilitating properties of MDD in the cognitive domain pose questions

concerning the underlying neurobiological mechanisms and efficacy of current therapies.
Wistar rats were subjected to social defeat-induced persistent stress (SDPS) paradigm, in which five defeat encounters are followed by ~3 months of social isolation. During the last 3 weeks of the paradigm, animals were provided with either antidepressant treatment (imipramine) or behavioral therapy (enriched environment). Effects of SDPS and of the two treatment regimes were examined at the behavioral (anhedonia, spatial memory), the electrophysiological (hippocampal long-term potentiation -LTP) and the molecular (hippocampal synaptic proteome) level.
SDPS animals displayed a sustained depressive-like state, including reduced reward anticipation (reflecting anhedonia), diminished hippocampal-dependent spatial recognition memory and reduced maintenance of hippocampus CA1 LTP. Both antidepressant and behavioral therapies were able to rescue the hippocampal LTP deficit and the observed cognitive impairments. Furthermore, the SDPS-induced depressive-like state was characterized by specific changes of the synaptic proteome of the dorsal hippocampus. We are currently assessing whether targeted interventions that reverse these changes can indeed prevent the depression-associated cognitive deficits and reduced plasticity.
Using the SDPS paradigm, an animal model that possesses high face, construct and predictive validity, we can mimic a maintained depressive-like state that models anhedonia and cognitive decline. Both antidepressant treatment and behavioral therapy seem promising on reversing these effects. The identification of the molecular mechanism by which hippocampal cognitive deficits and limited plasticity develop during this state of enduring depression hold great promise for future treatment strategies.

Title: Sex differences in the effects of intranasal oxytocin administration on social investigation in socially defeated California mice (Peromyscus californicus)

Authors: *M. Q. STEINMAN, C. E. MANNING, S. A. LAREDO, K. I. WALCH, B. C. TRAINOR;
Dept. of Psychology, Univ. of California, Davis, CA

Abstract: Women are twice as likely as men to be diagnosed with major depression and also respond more poorly to certain antidepressant drug treatments. Oxytocin (OT) is a neuropeptide that regulates mammalian social behavior and stress responses. Three consecutive days of social defeat stress reliably induces social withdrawal in female California mice (Peromyscus californicus), but not males. Interestingly, short term reactivity of OT neurons to defeat stress is similar in both sexes. In contrast, there are sex differences in long term changes in OT systems following defeat stress. Specifically, females but not males exposed to stress exhibit increased OT/c-fos colocalizations in a limbic region, the medioventral bed nucleus of the stria terminalis. Females also show reduced numbers of detectable OT neurons in the paraventricular nucleus of the hypothalamus, a stress responsive region that can release OT into systemic circulation as well as directly within the brain. We administered intranasal OT to males and females (low: 0.8 IU/kg; high: 8 IU/kg; or saline) 2 weeks after social defeat to examine the effects of OT on social interaction. Preliminary results indicate a significant sex*dose interaction on time spent near a novel mouse. Females given the low dose interacted less than females given the high dose or saline. There was a trend for the high dose to increase social interaction levels above saline controls, suggesting a U-shaped dose curve in females. The dose response differed greatly in males with the high dose appearing to decrease social interaction. There were no differences in time spent near an empty cage, suggesting that the effects of OT are specific to social contexts. We also assayed OT plasma levels at several time points. There was no immediate effect of social defeat on plasma OT levels nor were than long term changes in plasma OT levels in females. This suggests that it is unlikely that the increase in c-fos/OT colocalization during defeat reflects increased peripheral release. Furthermore it appears that the long term changes in female oxytocin neural circuits do not correspond with altered peripheral release. These results demonstrate that behavioral effects of oxytocin have different dose dependencies in males and females.

Title: Prenatal stress induces depressive-like behavior in a sex-specific manner; impact of familiar versus novel environments

Authors: *H. M. SICKMANN[1,2], T. S. ARENTZEN[2], M. P. KRISTENSEN[1], T. B. DYRBY[3], N. PLATH[2];
[1]Dept. of Drug Design and Pharmacol., Fac. of Hlth. Sci. , Univ. of Copenhagen, Copenhagen, Denmark; [2]H. Lundbeck A/S, Valby, Denmark; [3]Danish Res. Ctr. for Magnetic Imaging, Hvidovre Hosp., Hvidovre, Denmark

Abstract: Stress, including prenatal maternal stress, increases affective disorder morbidity. Furthermore, women appear twice as likely as men to develop stress- and depression-related disorders. Some of the behaviors associated with depression are also found in rat offspring following maternal prenatal stress (PS) incl. increased helplessness and altered anxiety response. Our purpose was to investigate behavioral depression indices following PS and potential differences between male and female offspring.
To this end, pregnant Sprague-Dawley rats were subjected to repeated variable stress on days 13-21 of gestation. The PS paradigm consisted of short-term stressors during the day (e.g. restraint, forced swimming, elevated platform placement) and a long-term stressor during the night (e.g. fasting, lights on). At post natal day 50-70, motor activity, depressive-like (forced swim test), anxiety-like (elevated plus maze, EPM), and sleep behavior (via EEG recordings) was assessed in male and female offspring. In addition, half of PS and control animals, respectively, were exposed to an acute stressor prior to the behavioral tests.
Weight gain during the last part of the pregnancy was significantly reduced in dams exposed to PS. Locomotor activity in a familiar environment (housing cage) during the rodent inactive phase was significantly enhanced in PS females compared to controls (Δ= 49 %, n = 15-37; $p < 0.001$). In contrast, PS decreased locomotor activity in male offspring during the rodent active phase (Δ= 18%, n = 11-33, $p = 0.04$), indicating that PS induces sex-specific behavioral changes. In the EPM, PS per se did not appear to change behavior in either sex. Exposure to an acute stressor, however, increased the amount of time spent in the open arm specifically in control males (Δ= 82%, n = 13-15; $p < 0.001$), and, interestingly, PS appeared to blunt this reaction (Δ= 21%, n = 5-6; $p < 0.36$). In summary, PS induces sex-specific behavioral changes where female offspring appears more vulnerable in a familiar environment whereas male offspring seems vulnerable in a novel environment. The central mechanisms mediating these differences may also contribute to sex-specific sensitivity to stressors and depression propensity in humans.

Title: Regulation of the serotonin autoreceptor (5-HT1A) and transporter (SERT) in the olfactory bulbectomy model of depression and following acute fluoxetine

Authors: M. RIAD[1], S. JOZAGHI[2], L. DESCARRIES[1], *S. M. BOYE[3];
[1]Pathology and Cell. Biol., [2]Physiol., [3]Psychiatry, Univ. of Montreal, Montreal, QC, Canada

Abstract: The 5-HT autoreceptor (5-HT1A) and plasmalemmal transporter (SERT) exert tight regulatory control over the activity of 5-HT neurons and appear pertinent to the underlying mechanisms of depression and antidepressant treatment. Previous work in rats has shown that acute treatment with the selective agonist 8-OH-DPAT or the selective 5-HT reuptake inhibitor (SSRI) fluoxetine, leads to internalization of 5-HT1A autoreceptors in 5-HT neurons of the dorsal raphe nucleus (DRN) but not in hippocampus (heteroreceptors). SERT is the primary target of SSRI antidepressants. Considerable evidence suggests that SERT too may be regulated and undergo adaptive changes in response to depression and SSRI treatment. An important shortcoming of these results is that they were obtained in normal rats. The aim of the present study was to investigate changes in the cellular distribution of 5-HT1A and SERT in a murine model of depression, olfactory bulbectomy (OBX). This pre-clinical model produces behavioral, neurochemical and endocrinological consequences that are qualitatively similar to depressive symptomatology. First, we validated our model by measuring locomotor activity in the open field. Two weeks following OBX, lesioned rats displayed the expected hyperresponsiveness to an anxiogenic environment. Animals were then injected with fluoxetine (10 mg/kg, i.p.) or vehicle and sacrificed after one hour. Second, the cellular and subcellular distribution of 5-HT1A and SERT were quantified using electron microscopy after immunogold labeling with specific antibodies against 5-HT1A or SERT, in rats with and without prior fluoxetine treatment and in a group of drug- and lesion-naïve rats. Our results show that in drug-naïve OBX rats, the density of plasmalemmal 5-HT1A autoreceptors is significantly increased in the dendrites of DRN (31% above control) but not in ventral hippocampus (CA3). Acute treatment with fluoxetine abolished

the OBX-induced increase. Quantification of SERT immunolabeling revealed a significant increase in plasmalemmal labeling in both DRN dendrites and hippocampal terminals of OBX rats (24% and 29% above control, respectively), an effect that was not altered by fluoxetine treatment at either site. Thus, the reduction in the plasmalemmal density of 5-HT1A following fluoxetine is consistent with internalization of the autoreceptor, an effect previously observed in normal rats. Further, the increased plasmalemmal density of 5-HT1A and SERT in OBX rats supports the hypothesis of reduced 5-HT function as a contributing factor to depression and further confirms OBX as a valid animal model.

Title: Ablation of serotonergic neurons in the dorsal raphe leads to anhedonia-like behavior in Wistar-Kyoto rats

Authors: *P. C. PUGH, N. L. JACKSON, I. A. KERMAN;
Psychiatry and Behavioral Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The serotonergic system plays an important role in a host of cognitive and affective functions, including behavioral arousal, homeostasis, sleep-wake regulation, exploration, and different aspects of depressive- and anxiety- like states. The primary source of brain serotonin (5-HT) is from the midline brainstem raphe nuclei, of which the dorsal raphe (DR) contains the greatest number of 5-HT neurons in the brain. Behavioral studies suggest that the DR modulates fear and anxiety-related behaviors; however, the current data are limited to studies that correlate activation of 5-HT neurons with various behaviors. We sought to determine whether elimination of 5-HT neurons in the DR leads to behavioral deficits that are confined to specific aspects of depressive- and anxiety- like states. We made stereotactic injections of the serotonergic toxin 5,7-dihydroxytryptamine (5,7-DHT) directly into the DR of Wistar-Kyoto (WKY) rats, with

control animals receiving an injection of saline of the same volume. After 7 days of recovery, the rats were subjected to a series of behavioral assessments. During the sucrose preference test, lesioned animals displayed lower sucrose preference (61.6 ± 12.5%, N=6) compared to saline-injected animals (92.7 ± 1.1, N=4, p=0.05). Within a social interaction paradigm, the lesioned animals also did not leave a neutral position any faster in the presence of a social partner (13.9 ± 6.9 sec, N=5) than they did for an empty cage (24.57 ± 9.573, N=6, p=0.409), while the sham animals more rapidly approached the social partner (4.9 ± 1.7 sec, N=5) than an empty cage (13.2 ± 2.9 sec, N=4, p=0.037). The animals with DR lesions did not significantly differ from control animals in the open field, elevated plus maze, novelty-suppressed feeding, or forced swim tests. After testing, the animals were sacrificed, and the lesions were confirmed by immunohistochemistry for tryptophan hydroxylase 2 (Tph2), the rate-limiting enzyme for the production of 5-HT in the brain. Our current studies suggest that the lesioning of 5-HT neurons in the DR specifically precipitates anhedonia-like behavior along with deficits in social interaction in the WKY rats. Further studies are underway to expand the cohort of animals and behaviors tested.

Title: Effects of maternal separation in behavior and cardiovascular system

Authors: *S. RANA[1], H. NAM[1], N. L. JACKSON[1], P. C. PUGH[1], J. M. WYSS[2], I. A. KERMAN[1];
[1]Dept. of Psychiatry and Behavioral Neurobiol., [2]Cell, Developmental and Integrative Biol., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Adverse life experiences during the early developmental period have been shown to have long-term effects on brain, behavior, physiological, and autonomic system in various animal species. Wistar Kyoto (WKY) rats are a proposed model of neuropsychiatric disorders that exhibit depressive and anxiety like behavior with enhanced stress reactivity. This study utilized maternal separation paradigm, a model of adverse early life experience on stress prone WKY rats to investigate the long-term effects on behavior and cardiovascular parameters. The

purpose of the study was to investigate the long term effects of maternal separation (180 min separation), maternal handling (15 min separation), and standard handling (no separation) on the behavior and cardiovascular system. Rat pups were separated from their dams either for 15 (MS15) or 180 (MS180) minutes from postnatal (P) days 1 through 14, whereas another group of rats which were not separated from their dams served as standard handling controls. When the rats reached adulthood (P55), all animals were subjected to a battery of behavioral tests including: novelty-suppressed feeding, open field, elevated plus maze, and social interaction tests to assay anxiety-like behavior. In addition, we utilized forced swim test to measure depressive like behavior. There were only few apparent behavioral differences in the MS15 or MS180 animals in the depressive and anxiety-like behaviors in WKY rats, possibly unsurprising given the baseline behavior of this line. A fraction of maternally-separated rats (MS15 and MS180, N=4 each) were implanted with telemetry pressure probes to obtain chronic cardiovascular measurements over time. Cardiovascular data showed a great level of individual variability in the pressure measurements (systolic, diastolic, and pulse pressures), but the heart rate did not exhibit such variability. No group differences were detected in the pressure parameters analyzed. However, we observed an interesting trend where the circadian periodicity of the mean arterial pressure decreased over time within the MS180 group. In addition, the MS180 rats tended towards an exaggerated tachycardiac response to acute stress (cage change). These preliminary findings suggest that maternally separated rats may exhibit exaggerated stress responses and furthermore might be vulnerable to cardiovascular dysfunction due to aging. We are currently expanding the cohort of animals used to further validate and expand these preliminary findings.

Title: Characterization of depressive- and anxiety-like behaviors in different rat strains

Authors: *H. NAM, N. L. JACKSON, P. C. PUGH, S. RANA, S. M. CLINTON, I. A. KERMAN;

Dept. of Psychiatry and Behavioral Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The Wistar-Kyoto rat (WKY) is a well-established animal model of depression and anxiety. Particularly, the WKY is known for its hyperactive neuroendocrine response to stress. In this study, we characterized WKY's depression- and anxiety-like behavior compared to 3 different strains of male rats (n=12 per strain) - the Spontaneous Hypertensive Rat (SHR), a closely related strain derived from the WKY; the Wistar, the outbred parent strain for both WKY and SHR; and the Sprague-Dawley (SD), an unrelated outbred strain that is widely used in biomedical research. Although behavior characteristics of the WKY rat have already been established, we sought to: 1) obtain further insight into their behavior profiles, including analysis of social interaction behavior and time-dependent changes in forced swimming behavior, not previously described; and 2) directly compare the behavior characteristics of two outbred rat strains that are commonly used as control strains. We replicated previous findings showing high levels of depressive- and anxiety-like behavior and decreased motor drive in WKY animals in the elevated plus maze test (EPM), the open field test (OFT), the novelty-suppressed feeding test (NSF), and the forced swim test (FST). Our data also suggest that the WKY rat has a distinct social interaction behavior profile, showing no preference towards novel male or female partner animals compared to a novel object. While showing similar interest toward the novel object as all the other strains, the WKY rat tended to stay away from the partner rats. In addition, our FST analysis indicates that the WKY rats are more immobile compared to other strains in the beginning of 15-min training phase and become even more immobile in the testing phase on the next day. The WKY rat has previously shown to readily adopt learned helplessness behavior by inescapable footshock paradigm, which is also considered as a depressive-like phenotype in rodents, and here we demonstrated similar behavioral characteristics by forced swimming. Two outbred strains, the Wistar and the SD, possessed similar behavioral characteristics across multiple behavioral tests, with slight differences in overall locomotion and stress-induced defecation. Together these data confirm that the WKY serves as a good animal model for studying depressive- and anxiety-like behaviors. Our future studies will focus on the central mechanisms that shape distinctive behavior profile of the WKY rat.

Title: The effects of fluoxetine and differential rearing on the expression of depressive-like states in male rats

Authors: *D. ARNDT, M. CAIN;
Psychology, Kansas State Univ., Manhattan, KS

Abstract: There are many factors that lead to the etiology of depression. Both the environment and serotonin can play a key role in the development of depression. Interestingly, many available antidepressant drugs reduce general locomotor behavior, while they increase escape-directed behavior in the forced swim test (FST), which is indicative of antidepressant-like states (Slattery & Cryan, 2012). The effects of environmental enrichment on FST performance remain unclear, from no effect (Cui et al. 2006) to the production of antidepressant-like states (Brenes et al. 2008; 2009). Likewise, the effects of isolation rearing on depressive-like states are inconsistent, from actually reducing despair (Wongwitdetcha et al. 2006) to increasing it (Heritch et al. 1990) depending upon the duration of the rearing period. Therefore, the current study investigated the effects of differential rearing and fluoxetine administration on locomotor behavior and FST performance. Male Sprague-Dawley rats arrived at the lab at 21 days of age and were randomly assigned to an enriched (EC) or isolated condition (IC) where they differentially reared for 30 days. The effect of fluoxetine (10 mg/kg, i.p.) on locomotor behavior was assessed during a 15-minute locomotor test session. Fluoxetine attenuated locomotor behavior in both EC and IC rats. The effect of fluoxetine on FST performance was then assessed through a 15-minute preswim followed 24 hours later by a 5-minute test session. Rats were subjected to a 15-minute preswim followed by 3 injections of fluoxetine (10 mg/kg, i.p.) or saline 23.5, 5, and 1 hour(s) before the 5-minute test session. All rats had an increase in immobility from the preswim to the test session. Fluoxetine did not, however, decrease immobility in either EC or IC rats compared to saline, suggesting that fluoxetine (10 mg/kg, i.p.) does not produce antidepressant-like effects in enriched or isolated rats. Interestingly, EC-saline and EC-fluoxetine rats exhibited more immobility than their IC counterparts. Additionally, differential rearing did not affect performance during the preswim session, indicating that 30 days of differential rearing does not alter baseline immobility. These results suggest that a 30 day rearing period increases depressive-like behaviors in enriched versus isolated rats in the FST. Therefore, a longer rearing period may be necessary to observe rearing-induced alterations in serotonergic functioning. A longer rearing period may result in both a protective effect of enrichment against depressive behaviors and an EC and IC divergence in the response to fluoxetine.

Title: Implications of NMDAR GluN2B subunits within the BNST in the antidepressant effects of ketamine

Authors: *K. LOUDERBACK[1,2,3,4], B. D. TURNER[2], T. L. FETTERLY[2], D. G. WINDER[1,3,2,4];
[1]Mol. Physiol. and Biophysics, [2]Brain Inst., [3]Neurosci. Program in Substance Abuse, [4]Kennedy Ctr., Vanderbilt Univ., Nashville, TN

Abstract: Low-dose ketamine induces rapid and long-lasting antidepressant effects in humans, and this effect has been replicated in rodent models of depression. The mechanisms of this antidepressant effect are not fully understood. Ketamine acts as a noncompetitive N-methyl D-aspartate receptor (NMDAR) antagonist, and studies have demonstrated that the ifenprodil derivative Ro 25-6981 (Ro), which inhibits GluN2B-containing NMDARs, is also capable of reducing depression-like behaviors in rodents. However, recent studies have shown that ifenprodil derivatives have a number of off-target effects at other sites critical for affective disorders, including the norepinephrine and serotonin transporters. Further, systemic administration of compounds such as ketamine and Ro does not allow determination of circuitry crucial for their actions. The GluN2B subunit is highly expressed in the bed nucleus of the stria terminalis (BNST), where it plays an important role in long-term potentiation (LTP). Given multiple studies implicating the BNST in negative affective disorders, we sought to explore the role of the GluN2B subunit within the BNST on affective behavior. First, we demonstrate that systemic ketamine (3mg/kg) and Ro (5mg/kg) decrease latency to feed in the Novelty-Induced Feeding Suppression (NIFS) behavioral paradigm following acute restraint stress. Interestingly, under similar conditions we did not find significant effects of either drug in the elevated zero maze (EZM) or forced swim test (FST). We next utilized a combination of floxed GluN2B mice and stereotaxic delivery of lentiviral Cre-recombinase to delete the grin2b gene specifically from the BNST (BNSTGluN2BKO). Similar to ketamine- and Ro-treated wild type mice, BNSTGluN2BKO mice have significantly reduced latency to feed in the NIFS paradigm but do not show alterations in the EZM or the FST. This effect was specific to GluN2B, as no effect was observed with similar LV-CRE injections into a homozygous floxed glucocorticoid receptor

mouse BNST. To determine the effects of BNST GluN2B deletion or systemic ketamine administration on plasticity within the BNST, we examined field potential induction of LTP in the BNST. We found that in BNSTGluN2BKO mice, an early component of LTP was enhanced compared to control virus (lentiviral GFP) injected mice. We have previously demonstrated that LTP in BNST is disrupted by prior stress. We are currently examining the impact of NMDAR inhibition and deletion on this disruption. In total, these data suggest that GluN2B containing NMDARs in the BNST play an important role in modulation of affective behavior.

Title: Serum microvesicle proteins as potential biomarkers for mayor depressive disorder

Authors: C. GÓMEZ-MOLINA[1], A. LUARTE[1], E. AMPUERO[1], M. SANTIBAÑEZ[1], *U. WYNEKEN[2];
[1]Univ. de Los Andes, Santiago, Chile; [2]Univ. De Los Andes, Santiago, RM, Chile

Abstract: Mayor depressive disorder (MDD) is a multifactorial disease with increasing evidence for the existence of sub-types. As the disease has no clear etiology so far, it is even harder to diagnose subtypes with objective criteria, which in turn will determine the election of appropriate treatments. Animal models of MDD are based on exposure to chronic stress. Previous work in our laboratory demonstrated that two MDD animal models based on movement reduction, either by restriction (RS) in small cages or immobilization (IS) in plastic bags, respond differentially to two antidepressant drugs (ADD), fluoxetine (flx, a serotonin reuptake inhibitor), and reboxetine (rbx, a noradrenaline reuptake inhibitor). We therefore searched for protein markers in the cerebrospinal fluid (CSF) and blood serum to help in the characterization of both models. In the CSF, the metabolic enzyme fructose 1, 6-bisphosphate aldolase C (AldoC), expressed in forebrain astrocytes, was highly increased in the CSF after RS, but not after IS. Based on this, we isolated serum microvesicles and found by western blots that AldoC was present after RS. A second protein differentially present in serum microvesicles of RS animals was Leucin Rich Repeat Neuronal protein 3 (LRRN3), an orphan receptor mainly expressed in brain. Our results

show that serum microvesicles provide a novel and useful tool to identify protein markers present in MDD models, which could in turn help define protein markers for stress induced depressive disorder.

Title: Behavioral roles of cannabinoid type 2 receptor in depression

Authors: *H. ISHIGURO[1,2], K. TABATA[1], N. E. BUCKLEY[3], T. UEMURA[1], N. MOTOHASHI[1], Q.-R. LIU[4], E. S. ONAIVI[2];
[1]Univ. of Yamanashi, Chuo, Yamanashi, Japan; [2]William Paterson Univ., Wayne, NJ; [3]California State Polytechnic Univ., Pomona, CA; [4]NIDA-IRP/NIH, Baltimore, MD

Abstract: Major depression, addiction and other psychiatric diseases are mental health problems associated with stressful events in life with high relapse and recurrence even after treatment. In our previous study, we have demonstrated a high incidence of Q63R polymorphism in the Cannabinoid CB2 Receptor gene (CNR2) in depression, schizophrenia and alcoholics in Japanese population. The receptors are expressed in the brains of mice and rats, and are modulated following exposure to stressors and administration of drugs of abuse. C57BL/6J inbred mice with reduced Cnr2 expression in midbrain appeared to drink more alcohol. Therefore, we further examined a functional relationship of Cb2 receptor in mice, using depression models in this study. C57BL/6J mice subjected to chronic mild stressors for 2 weeks showed higher anxiety in Zero maze test. While Cb2 inverse agonist AM630 increased their anxiety, the agonist JWH015 reduced the anxiety, which was similar to the effect of fluvoxamine. In another study, Poly-IC was injected i.p. to Cnr2 knockout mice, and their

locomotor activity was measured 6, 24, and 48 hours after the injection and compared with those of the wild type controls. Locomotor activity of the mutant mice was relatively maintained in the test cage, in comparison to the activity of the wild type mice that were depressed by Poly-IC. It was interpreted that mice reduced Cb2 function
could not settle themselves down in unfamiliar places following treatment with Poly-IC. The components of the endocannabinoid system may have a role in onset and relapse of stress-related disorders and in some psychiatric diseases. Therefore, CB2 cannabinoid receptors may be a therapeutic target in those psychiatric diseases.

Title: Ultrasonic vocalizations during intermittent swim stress forecast resilience in subsequent forced swim and spatial learning tests

Authors: *R. C. DRUGAN, T. A. PAPALLO, L. L. CASTRACANE, T. A. WARNER, N. P. STAFFORD;
Dept Psychol, Univ. New Hampshire, DURHAM, NH

Abstract: We previously reported that ultrasonic vocalizations (USVs) during exposure to intermittent swim stress (ISS) predicted protection against stress-induced deficits in an instrumental swim escape test. We now extend these preliminary findings by reporting that rats emitting USVs during ISS also show resistance to stress-induced immobility in the forced swim test (FST) and spatial learning deficits in the Morris water maze (MWM). Rats were exposed to either 80-5 sec exposures to cold water swims (average of one per min, ISS) or run through the procedure in the absence of water (confined control, CC). We recorded the number and duration of ultrasonic vocalizations by a high frequency microphone connected to a computerized data capture system (Labview). Experiment #1: twenty-four hours later separate groups of both ISS and CC rats were exposed to a 5 min forced swim test and behaviors (e.g., swimming, climbing, immobility) were scored during FST. For Experiment #2, twenty-four hours post ISS, spatial learning was assessed in the MWM (18 massed trials). In both experiments, only a small number

of rats emitted USVs during the ISS. However, every one that vocalized showed reduced immobility in the FST and proficient spatial learning in the MWM. These findings provide further evidence that this non-invasive measure serves as a predictor of future resilience, may uncover previously unappreciated neural systems associated with resilience, and hasten novel drug discovery and more effective pharmacotherapy for depression.

Title: Mechanisms underlying the effects of vagal nerve stimulation

Authors: *A. P. SHAH, Y. CHUNG, F. R. CARRENO, A. FRAZER;
Pharmacol., Univ. of Texas Hlth. Sci. Ctr. At San Antonio, SAN ANTONIO, TX

Abstract: Vagal nerve stimulation (VNS) is an FDA-approved therapy for treatment resistant depression (TRD). Whereas there is an anatomical rationale for the antidepressant-like effects of VNS, the molecular mechanisms underlying these effects have not been characterized in depth. We have shown that similar to classical antidepressant drugs, acute or chronic administration of VNS causes activation of TrkB, the receptor for BDNF and NT-4/5. However, the role of this receptor in the behavioral effects of VNS remained to be investigated. We have addressed this question using K252a, a non specific tyrosine kinase inhibitor that targets TrkB and have used the Novelty Suppressed Feeding Test (NSFT) as the behavioral output. We have previously shown that chronic VNS (10 days), like desipramine (DMI), leads to a reduction in latency to eat familiar food in a novel box which is indicative of an anxiolytic-like effect of the treatment. We now find that this effect of chronic VNS is blocked after repeated intracerebroventricular injections of K252a. Interestingly, neither the anxiolytic-like effect (in the NSFT) nor the antidepressant-like effect (in the Forced Swim Test) of DMI was blocked by K252a. Food consumption within the home cage and locomotor activity were monitored in order to control for confounding effects of the drugs/VNS. These observations highlight a difference in the mechanisms of action of VNS and antidepressant drugs.
In order to explore the broader effects of VNS and compare these with effects of antidepressant

drugs, we have carried out whole genome microarray studies using hippocampal tissue from animals that have been chronically treated with VNS or DMI. Preliminary analysis reveals changes ($p<0.05$ and fold change>1.5) in expression of potentially relevant genes in response to VNS. For instance, expression of the gene, *Ttr* is significantly upregulated 16.7-fold ($p=1.24x10^{-7}$). *Ttr* codes for transthyretin, which binds to and transports thyroxine and retinol. Clinical studies have shown that depressed patients have low CSF levels of transthyretin.

Title: Effects of SSRI and SNRI antidepressant drugs on schedule-induced polydipsia in rats: Evaluation of α2 adrenoceptor antagonism with yohimbine

Authors: S. M. MOONEY-LEBER[1], M. D. BERQUIST, II[1], A. L. PEHRSON[2], N. P. PORTER[3], J. H. PORTER[3], *A. PRUS[1];

Abstract: Antidepressant drugs require several weeks to exhibit efficacy for the treatment of depression or anxiety disorders. This delayed onset appears to be modeled in the schedule-induced polydipsia paradigm in rodents, in which several days of antidepressant administration may be necessary to significantly reduce water consumption. The present study sought to replicate an inhibition in scheduled-induced water consumption in rats observed after several days of the selective serotonin reuptake inhibitor (SSRI) fluoxetine administration as reported in earlier studies, as well as to extend these previous findings by evaluating the serotonin-norepinephrine reuptake inhibitor (SNRI) duloxetine. Further, given that α2 adrenoceptor desensitization may contribute to the antidepressant effects of duloxetine, the present study also sought to determine if administration of the alpha2 adrenoceptor antagonist yohimbine could potentiate fluoxetine's effects on schedule induced polydipsia. In Experiment 1 a 10.0 mg/kg dose (p.o.) of fluoxetine required 6 days of repeated administration to significantly reduce water

consumption; whereas, a 30.0 mg/kg dose significantly reduced water consumption on day 1. A 30.0 and 100.0 mg/kg dose of duloxetine (p.o.) decreased water consumption after 3 days and 1 day, respectively. In Experiment 2 a dose of 4.0 mg/kg (i.p.) fluoxetine failed to significantly reduce water consumption over 6 days of injections; whereas, an 8.0 mg/kg dose reduced water consumption on day 3. Co-administration of the sub-effective 4.0 mg/kg dose of the SSRI fluoxetine with sub-effective doses of yohimbine (1.25 and 2.5 mg/kg) led to a significant decrease in water consumption on the second day of administration with 1.25 mg/kg yohimbine and on the first day of administration with 2.5 mg/kg yohimbine. The present results confirm previous findings that inhibition of serotonin reuptake alone is sufficient to reduce water consumption in the schedule-induced polydipsia paradigm. In addition, the results for the α2 antagonist yohimbine (in combination with fluoxetine) support the suggestion that blockade of α2 adrenoceptors may significantly reduce the response time for antidepressant efficacy in humans.

Title: Identification of a stress-vulnerable, treatment-resistant, ketamine-sensitive genetic line in the chick anxiety-depression model

Authors: *S. W. WHITE[1], K. J. SUFKA[1,2,3];
[1]Dept. of Psychology, Univ. of Mississippi, University, MS; [2]Res. Inst. of Pharmaceut. Sci., [3]Dept. of Pharmacol., Univ. of Mississippi, Univeristy, MS

Abstract: Current antidepressant pharmacotherapies lack effectiveness in significant portions of patients suffering from major depression. Many in this clinical population show stress-vulnerability and treatment-resistance (failure to respond to two classes of FDA approved antidepressants), but do respond to the *N*-Methyl-D-aspartate (NMDA) antagonist ketamine. The introduction of novel therapies for treatment-resistant depression is hindered by translational challenges with existing preclinical screening models. Recent research in the chick anxiety-depression model identified two strains in which one displays stress vulnerability (Black Australorp) and the second stress resilience (Production Red) as measured by onset of behavioral

despair. This current study sought to explore whether these two lines display differential sensitivities to the tricyclic antidepressant (TCA) imipramine, the selective norepinephrine reuptake inhibitor (SNRI) maprotiline, the selective serotonin reuptake inhibitor (SSRI) fluoxetine, and ketamine. Socially-raised chicks (Ideal Poultry, Cameron, TX) were tested in isolation (90 m) in separate sound-attenuating chambers at 5-6 d post-hatch 15 m after receiving IP injections of vehicle or one of several doses of drug probes. Distress vocalization served as the dependent measure. Here, we replicate the Black Australorp strain is vulnerable to isolation stress. Further, this strain is also treatment resistant to imipramine and fluoxetine but shows antidepressant sensitivity to ketamine. Our findings suggest that the chick anxiety-depression model using the Black Australorp line may prove useful in pre-clinical screening of novel antidepressant targets for use in treatment-resistant depression.

Title: Antidepressant effects of resveratrol in an animal model of depression

Authors: *L. L. HURLEY, L. AKINFIRESOYE, O. KALEJAIYE, Y. TIZABI;
Pharmacol., Howard Univ., WASHINGTON, DC

Abstract: Resveratrol (3, 4', 5-trihydroxy-trans-stilbene) is a natural non-flavonoid polyphenol antioxidant extracted from red grapes in the processing of wine. Initially it was studied for its potential as anticancer drug, and later was recognized for its ability to reduce cardiovascular disease. More recently resveratrol was shown to alleviate depressive-like symptoms in mice, postulated to be due to its induction of central biogenic amines and a decrease in neuro-inflammatory markers. The purpose of this study was to investigate whether resveratrol would manifest an antidepressant effect in Wistar-Kyoto rats, a putative and non-induced animal model of depression, which are resistant to conventional selective serotonin reuptake inhibitors (SSRIs).

Additionally, since hippocampal brain-derived neurotrophic factor (BDNF) has been implicated in antidepressant effects of many drugs, we evaluated the level of this protein in both the hippocampus and frontal cortex. Adult male WKY rats were subjected to two doses of resveratrol (10 and 40 mg/kg, i.p.) and their behavior in the open field locomotor activity (OFLA), forced swim test (FST: a measure of helplessness), and sucrose preference test (SPT: a measure of anhedonia) was evaluated after a single acute injection (20 min) or 18-20 h following the last of 7 daily injections. Both acute and chronic treatment with resveratrol resulted in a dose-dependent decrease in FST, and chronic treatment with the higher dose increased sucrose consumption. OFLA was not affected by any dose of resveratrol. Parallel to the observed behavioral effects, the level of hippocampal BDNF, but not frontal cortex, was also dose-dependently elevated after chronic resveratrol administration. These findings support an antidepressant-like effect of resveratrol, possibly mediated through hippocampal BDNF. Thus, resveratrol may have therapeutic potential, particularly in at least the subpopulation of treatment resistant depressed patients.

Title: Nicoitne blocks alcohol-induced decreases in hippocampal BDNF and synapsin: Implication for smoking-drinking co-morbidity

Authors: *O. O. KALEJAIYE, R. E. TAYLOR, Y. TIZABI;
Pharmacol., Howard Univ. Col. of Med., Washington, DC

Abstract: We have reported that nicotine attenuates alcohol-induced depression in Wistar rats and hence the opposing effects of these two substances on mood may be a contributory factor to their co-abuse (Kalejaye et al SFN abst 2012). Although the exact neurobiological substrates of depression in general, and alcohol-induced depression in particular, are not known, it has been suggested that the action of brain derived neurotrophic factor in different brain regions and specifically in hippocampus may be crucial in mood regulation and effectiveness of antidepressants. In addition, changes in synaptogenesis have been implicated in mechanism of fast acting antidepressants. Here, we sought to determine whether alcohol-induced depression is associated with a reduction in hippocampal BDNF and/or synaptogenesis, and whether nicotine may attenuate these neurochemical effects of alcohol. Adult male Wistar rats were injected (i.p.) with alcohol (1.0 g/kg), nicotine (0.3 mg/kg) or their combination once daily for 21 days. Controls received saline. These injections were identical to the previously evaluated behavioral effects where the helplessness and anhedonia induced by alcohol were shown to be attenuated by nicotine. In this case, however the rats were sacrificed 24 after the last injection for measurement of hippocampal BDNF and synapsin, a marker of synaptogenesis. These proteins were evaluated by Western blot. Parallel to the behavioral changes chronic alcohol resulted in significant decreases in hippocampal BDNF and synapsin. Nicotine by itself did not affect the levels of these markers, but completely blocked the effects of alcohol. Thus, hippocampal changes in neurogenesis and synaptogenis may underlie alcohol-induced depression and their normalization by nicotine may underlie the effectiveness of nicotine as an antidepressant.

Title: Sex-specific regulation of the microRNA transcriptome by stress

Authors: *M. L. PFAU, G. E. HODES, J. FENG, S. A. GOLDEN, H. M. CATES, D. J. CHRISTOFFEL, M. HESHMATI, H. ALEYASIN, L. SHEN, S. J. RUSSO;
Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Adult women are twice as likely as men to develop major depression, although the precise molecular mechanisms underlying sexual dimorphism in depression susceptibility are unknown. We have developed a stress paradigm—subchronic variable stress (SCVS)—to model these sex differences in mice. Female mice subjected to SCVS exhibit depression-like behavior after 6 days of stress exposure, whereas male mice exhibit depression-like behavior only after 28 days of variable stress. Thus, this model has validity with relation to the increased prevalence of stress disorders in women. To identify the potential mechanisms driving these behavioral differences, we have profiled sex differences in gene expression in the mouse nucleus accumbens (NAc) following SVCS using next generation mRNA sequencing (RNA-Seq). We found that males exhibit a robust transcriptional response to 6-day SCVS. However, less than 3% of the stress-regulated genes identified by RNA-Seq were similar between the sexes. To examine potential mechanisms regulating this sex difference in transcriptional response to stress, we have performed next generation small RNA-Seq on NAc tissue from intact male and female mice subjected to SCVS. Here, we report significant sex differences in microRNA transcriptional profiles that correlate with behavioral susceptibility or resilience to stress and mRNA transcription patterns.

Title: Hypobaric hypoxia induces depression-like behavior in female but not male Sprague Dawley rats

Authors: *S. KANEKAR[1,2], P. OLSON[1], O. BOGDANOVA[1], K. D'ANCI[3,4], P. RENSHAW[1,2]; [1]Brain Inst., [2]Dept. of Psychiatry, Univ. of Utah, Salt Lake City, UT; [3]Dept. of Psychology, Tufts Univ., Medford, MA; [4]Dept. of Psychology, Salem State Univ., Salem, MA

Abstract: Demographic studies show that higher rates of depression and suicide, the most adverse impact of unresolved depression, correlate with altitude of residence. Selective serotonin reuptake inhibitors (SSRIs), the most commonly prescribed antidepressants, function by increasing synaptic exposure to serotonin. However, living at altitude exposes people to hypobaric hypoxia, which lowers rat brain serotonin levels, and SSRIs show low efficacy in mice with low brain serotonin. Hypobaric hypoxia may thus reduce SSRI efficacy, likely causing higher rates of SSRI-resistant depression at altitude. We have established an animal model for altitude-related depression to study SSRI efficacy at altitude. We first determined whether hypobaric hypoxia can induce depression-like behavior in rats. Sprague Dawley rats were housed at altitude simulations of 20,000 ft (20K), 10,000 ft (10K) or sea level (SL) using altitude chambers, or at local conditions of 4,500 ft (4.5K, altitude of Salt Lake City, UT) for 1 week. Rats were then tested in the forced swim test (FST), an established behavioral test used to identify depression-like behavior and screen antidepressants in rats. Behavior in the FST was scored as time spent swimming, climbing or immobile, and latency to immobility was measured. Increased immobility and reduced latency to immobility in the FST are viewed as signs of depression-like behavior. Results: Female rats exhibit incrementally more depression-like behavior with exposure to altitude for a week, while males do not. Females housed at SL (n=10) spent 50% of their time in the FST in active, escape-seeking behavior, which dropped to 33% in the 4.5K group (n=24), and to 21% in 10K (n=9) or 20K (n=11) groups. Female rats at altitude exhibit incrementally more immobility ($F(3, 50)=5.2$, $p=0.007$) and lower latency to immobility ($F(3, 50)=10.9$, $p<0.0001$) (p values corrected with Bonferroni post-hoc test). Females at altitude swam less than those at SL ($F(3, 50)=11.7$, $p<0.0001$) while climbing was unchanged, implying that hypobaric hypoxia impacts brain serotonin but not dopamine levels. In contrast, male rats in the SL (n=11), 4.5K (n=16) or 20K (n=10) groups exhibit identical FST behavior: 23-25% of time spent active and 75-77% immobile, with a similar latency to immobility across groups. Gender differences in depression, antidepressant response, and serotonin turnover are seen in both animal (Dalla et al., 2009) and clinical studies (Keers et al., 2010), implying the potential use of a gender-based approach to antidepressant therapy. Analysis of brain monoamines in the 4 altitude groups and SSRI efficacy tests at altitude are in progress. Funded by USTAR and VISN19 MIRECC.

Title: Dissociable effects of the noncompetitive NMDA antagonists ketamine, phencyclidine (PCP), MK-801, and other glutamatergic ligands in the differential-reinforcement-of-low-rate (DRL) 72 sec task

Authors: *B. L. JOSEPH, T. M. HILLHOUSE, F. F. STEELE, J. H. PORTER;
Psychology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Major depressive disorder (MDD) is the most common mood disorder in the United States with approximately 36% of MDD patients categorized as being treatment resistant (i.e. no/minimal symptom reduction after adequate treatment duration). Clinical research has demonstrated that ketamine produces rapid and prolonged antidepressant effects in treatment-resistant patients. Preclinical research is currently evaluating the possible underlying mechanism(s) responsible for these robust antidepressant effects. Our laboratory has previously shown that the noncompetitive N-Methyl-D-aspartate (NMDA) antagonist ketamine produces antidepressant-like effects in the differential-reinforcement-of-low-rate (DRL) 72 sec operant task, which has been used to selectively screen antidepressant drugs since the 1980's. A ligand demonstrates antidepressant-like effects in this preclinical assay if the number of reinforcers earned are increased, responses emitted are decreased, and produces a rightward shift in the interresponse times (IRT) distribution. The aim of the present study was to determine if the antidepressant-like effects of ketamine in the DRL 72 sec task are unique to ketamine or shared by other noncompetitive NMDA antagonist (i.e. phencyclidine (PCP) and MK-801), as well as other glutamatergic ligands. Ketamine (10.0 mg/kg) produced an antidepressant-like effect in the DRL-72 sec task by increasing the number of reinforcers earned, decreasing the number of responses emitted, and producing a rightward shift in the IRT distribution. The high dose of PCP (10.0 mg/kg) disrupted behavioral responding and did not demonstrate an antidepressant profile in the DRL 72 sec task. Conversely, MK-801 (0.05 and 0.1) produced a psychostimulant-like effect by decreasing the number of reinforcers earned, increasing the number of responses emitted, and producing a leftward shift in the IRT distribution. The remaining glutamatergic ligands tested appear to have mixed results. These data indicate that ketamine, PCP, and MK-801 produced dissociable effects in the DRL-72 sec task and further suggest that ketamine may have greater antidepressant efficacy. Additionally, these results suggest that the underlying mechanism responsible for the antidepressant effects of ketamine may be unique to ketamine and not to all NMDA antagonists.

Title: The noncompetitive NMDA antagonist ketamine, but not MK-801, produces antidepressant-like effects in rats responding on a differential-reinforcement-of-low-rate (DRL) 72 second operant schedule

Authors: *J. H. PORTER, T. M. HILLHOUSE;
Psychology, Virginia Commonwealth Univ., Richmond, VA

Abstract: Major depressive disorder (MDD) is the most common mood disorder in the United States with a lifetime and 12-month prevalence of 16.6% and 7.1%, respectively. Current antidepressant treatments primarily target the monoamine neurotransmitters (i.e. serotonin, norepinephrine, and dopamine) in an attempt to enhance the presence of monoamine neurotransmitters in the synaptic space. Unfortunately, approximately 36% of patients are treatment resistant (i.e. they fail to response to 2 or more antidepressant treatments). The noncompetitive N-Methyl-D-aspartate (NMDA) antagonist ketamine has been shown to produce rapid and prolonged antidepressant effects in treatment-resistant MDD patients following both single and repeated administration of a low, subanesthetic dose. The current study evaluated the antidepressant effects of ketamine and the more potent and selective noncompetitive NMDA antagonist MK-801 (dizocilpine) using the differential-reinforcement-of-low-rate (DRL) 72 sec operant task in rats. Ligands demonstrate antidepressant-like effects in this preclinical assay if the number of reinforcers earned are increased, responses emitted are decreased, and produces a rightward shift in the interresponse times (IRT) distribution. The noncompetitive NMDA antagonist ketamine (10.0 mg/kg) and the agonist NMDA (30.0 mg/kg) significantly increased reinforcers, decreased responding, and produced a rightward shift in the IRT distribution. MK-801 produced psychostimulant-like effects by decreasing reinforcers, increasing responses, and producing a leftward shift in the IRT distribution. The tricyclic antidepressant imipramine and the selective serotonin reuptake inhibitor fluoxetine both produced antidepressant-like effects; whereas, the dopamine agonist d-amphetamine produced psychostimulant-like effects similar to the effects produced by MK-801. Combination testing revealed that a sub-effective dose of ketamine (3.0 mg/kg) antagonized the antidepressant-like effects of NMDA (30.0 mg/kg). However, a sub-effective dose of NMDA (10.0 mg/kg) had no effect on the antidepressant-like effects of ketamine (10.0 mg/kg). While it may seem counterintuitive for both an antagonist and

agonist at the same receptor to produce similar effects, ketamine and NMDA have different binding sites at the NMDA receptor and may work through different mechanisms. Ketamine and MK-801 produced dissociable effects in the DRL-72 sec task and this suggests that the antidepressant effects of ketamine may be mediated by pharmacological mechanism(s) exclusive to ketamine, but not other NMDA antagonists.

Title: The role of FGF2-AS in stress and depression-like behavior in rats

Authors: *E. EREN KOCAK[1,2], K. BASAR[2], M. YILMAZ[1], Y. AYHAN[2], T. DALKARA[1,3]; [1]Inst. of Neurolog. Sci. and Psychiatry, [2]Dept. of Psychiatry, Fac. of Med., [3]Dept. of Neurology, Fac. of Med., Hacettepe Univ., Ankara, Turkey

Abstract: There is a growing body of evidence on the association of FGF2 with depression. For example, chronic stress decreases and antidepressant administration increases FGF2 expression in the prefrontal cortex and hippocampus. Moreover systemic and intracerebroventricular (icv) administration of FGF2 has been shown to have antidepressant effects. Unlike most mammalian genes, antisense (AS) strand of the FGF2 gene is also transcribed into an RNA (FGF2-AS) that is thought to regulate the expression of FGF2. We hypothesized that chronic stress would increase FGF2-AS levels and overexpression of FGF2-AS would have depressogenic effects. First we investigated the effects of chronic restraint stress on the expression of FGF2 and FGF2-AS in male Sprague Dawley rats at three time points: 2h, 6h and 24h after the last stress. Interestingly we found a decrease in the protein expression of both FGF2 and FGF2-AS in the prefrontal cortex following chronic stress exposure. Then we investigated the effects of FGF2-AS overexpression by repeated icv injections of an expression vector bearing FGF2-AS. We found that FGF2-AS overexpression decreases immobility time in forced swim test (FST). Our findings indicate that FGF2-AS is important for the regulation of mood. Contrary to our hypothesis, chronic increase in the expression of FGF2-AS has antidepressant effects on FST, similar to the effects of FGF2.

Title: An animal model of recurrent depression: sensitized depression-like behavior when rats are re-exposed to chronic mild stress

Authors: *J. L. REMUS, D. JAMISON, J. D. JOHNSON;
Biol. Sci., Kent State Univ., Kent, OH

Abstract: Major depression is a debilitating disorder, characterized by feelings of worthlessness, persistent sadness and lack of motivation. Depression is also recognized to be a chronic, recurrent disorder, and each depressive episode increases an individual's susceptibility to future occurrences. The current study aimed to develop an animal model of recurrent depression in order to examine possible biological mechanisms responsible for this increased susceptibility. We hypothesized that animals with a prior depressive episode would be sensitive to future stressors, causing the animals to display depressive-like behaviors more rapidly or to a greater extent. Fisher rats (n=15) were exposed to chronic mild stress for 35 days or remained in their home cage as controls. During the initial stress, animals showed a slow decrease in sucrose consumption. Following the 35 days, animals went through a 20 day recovery phase where no stressors were present and animal showed a steady increase in sucrose consumption back to baseline levels. At this time animals were re-exposed to the chronic mild stress for 15 days. A rapid decline in sucrose consumption was observed. Linear regression lines were calculated for each animal's sucrose consumption during the first and second stressor exposure and a paired t-test of the slope of each line revealed re-exposure to stress resulted in a significantly more rapid decline in sucrose consumption compared to that observed during the initial stressor exposure.

Title: Phospholipase D - mTOR signaling is compromised in a rat model of depression

Authors: *P. FENG, Y. HU, C. HUANG;
Res., Case Western Reserve Univ/Cleveland VA, CLEVELAND, OH

Abstract: Depression is associated with structural and neurochemical changes in limbic structures, including the hippocampus, that control emotion and mood. Structural abnormalities such as decrease in hippocampal cell proliferation, neurogenesis and hippocampal volume, and loss of neurons and glial cells have been widely reported in physical and psychosocial stress paradigms and animal model of depression, but corresponding neurochemical changes are largely unknown. Using neonatal clomipramine (CL)-treated rats as a model to elucidate the association of phospholipase D (PLD) and mammalian target of rapamycin (mTOR) signaling with depressive pathology, we found that the hippocampus of CL-treated rats showed significantly down-regulation of PLD1 expression and attenuation of PLD activity which leads to the less formation of phosphatidic acid (PA), an activator of mTOR, and free choline, a potential biomarker for depression. With lower PA levels which could affect mTOR signaling, we further observed that the phosphorylation of p70S6 kinase, one of the downstream effecors of mTOR, was also significantly decreased in the hippocampus of CL-treated rats compared to the controls. Down-regulation of PLD1 expression, PLD activity and p70S6 phosphorylation was also found in the hypothalamus and frontal cortex with CL-treated rats. Our results indicate that PLD-mTOR signaling is associated with depressive disorder.

Abstract: Antidepressants increase neurogenesis in adult dentate gyrus (DG), which is considered to be involved in the therapeutic action of antidepressants. However, the mechanism underlying it remains unclear. Using the culture system of adult rat DG-derived neural precursor cells (ADP), we have already reported that antidepressants have no direct effects on ADP. Therefore, antidepressants may increase neurogenesis in adult DG with unknown indirect mechanisms. We have also reported that amitriptyline (AMI), a tricyclic antidepressant, increases the secretion of GDNF, BDNF, FGF2 and VEGF from primary cultured astrocytes (PCA). All of GDNF, BDNF, FGF2 and VEGF increase in vivo neurogenesis in DG of adult rodents. These suggest that AMI-induced factors in astrocytes may increase neural precursor cells in adult DG. To examine this hypothesis, we examined the effects of GDNF, BDNF, FGF2, VEGF and conditioned medium (CM) from PCA treated with AMI on ADP proliferation.
ADP were prepared from adult DG of adult rat and cultured with Neurobasal-based medium. PCA were prepared from hippocampus of postnatal rat and cultured with DMEM-based medium. CM was prepared by culturing PCA with Neurobasal-based medium. When the effects of CM on ADP proliferation, CM and Neurobasal-based medium were equally mixed. The effects of CM, factors and drugs on ADP proliferation were examined with BrdU immunostaining.
AMI had no direct effect on ADP proliferation, but AMI-treated CM increased ADP proliferation in response to concentrations of AMI treated in PCA. Thus, AMI may indirectly increase ADP proliferation through inducing BDNF, GDNF, FGF2 and/or VEGF from PCA. Next, the expression of the receptors of BDNF, GDNF, FGF2 and VEGF in ADP were examined with RT-PCR. The receptors of GDNF, BDNF and FGF2, but not VEGF, were expressed in ADP. Following it, the direct effects of BDNF, GDNF and FGF2 on ADP proliferation were examined. Only FGF2 significantly increased ADP proliferation. To confirm that AMI-induced FGF2 surely mediates the increasing effects of AMI-treated CM on ADP proliferation, the effects of SU5402, a specific inhibitor of FGF receptors and anti-FGF2 antibody on ADP proliferation were examined. Both SU5402 and anti-FGF2 antibody significantly canceled the increasing effects of AMI-treated CM on ADP proliferation.
Our present study has shown that AMI indirectly increases ADP proliferation via inducing FGF2 secretion from PCA. FGF2 in brain is mainly derived from astrocytes. Astrocyte is a key component of the neurogenic niches in adult DG. Therefore, antidepressants may increase in vivo neurogenesis in adult DG through inducing FGF2 secretion from astrocytes.
